Chapter 1

General introduction

1.1 Biodiversity

The evolutionary processes that have led to the astonishing high diversity of tropical rain forests have long fascinated biologists. Understanding these processes is pivotal to shed light on our knowledge of Earth's species (Mora et al. 2011), to identify biodiversity hotspot (Myers et al. 2000; Joppa et al. 2010), and for the determination of the most appropriate conservation strategy (Morley 2000; Sechrest et al. 2002). The global debate on climatic change makes such an understanding even more urgent. Indeed, human activities such as logging, mining or the conversion of forest for agriculture have led to the fragmentation and alteration of many tropical forest areas (Malhi et al. 2008; Hector et al. 2011; Brando et al. 2013; Mayaux et al. 2013; Rudel 2013). These activities contribute to huge biodiversity losses (Wilson 1992; Pimm et al. 1995) and the rise in atmospheric carbon dioxide (Brown 1993; Malhi and Grace 2000) due to the conversion of high-carbon storage of intact forest to low-carbon storage of alternative land-use (Lewis 2006), resulting in climate change (Malhi et al. 2013). Such change may in itself lead to even more severe losses of biodiversity, and hence the study of the diversity and evolution of tropical forests is at the centre of global attention.

Tropical forests cover only ca. 10% of the Earth's land surface (Lewis 2006), but house between half and two thirds of the world's species (Malhi and Grace 2000; Groombridge and Jenkins 2003), suggesting that most of them are still unknown to science (Joppa et al. 2011). Therefore, fundamental research to discover and document tropical forest diversity is still urgently needed to underpin its conservation and sustainable utilization (Mora et al. 2011; Daly et al. 2012).

In Africa, the most species-rich tropical forests are found in the Lower Guinea phytogeographical region (White 1983; Linder, Lovett, et al. 2005; Linder et al. 2012), covering south-eastern Nigeria, Cameroon, Gabon, Congo (Brazzaville) and western Democratic Republic of Congo, and show the highest concentration of endemics (Barthlott et al. 1996; Linder 1998; Cheek et al. 2001; Linder 2001; Mutke et al. 2001; La Ferla et al. 2002). The lowland rain forests of Gabon are reputedly the richest in plant species of the whole of Africa (Breteler 1990; Linder 2001; Mutke et al. 2001; Küper et al. 2004; Sosef et al. 2006; Estrella de la et al. 2012; Linder et al. 2012). From this country alone, several plant species new to science are discovered each year e.g. (Jongkind 2005; Bissiengou and Sosef 2008; Ntore et al. 2009; F. J. Breteler 2011; Lachenaud and Breteler 2011; Van der Maesen and Walters 2011; Sosef and Dauby 2012; Bissiengou et al. 2013; Breteler 2013; Sosef 2013; Van der Maesen 2013). Nonetheless, the area is still botanically under-explored (Sosef et al. 2006; Van der Maesen and Walters 2011), and many species are poorly known or remain hidden for mankind as yet.

Within the Ochnaceae family, the genus *Campylospermum* is one of these groups of plant that show their highest diversity in the Lower Guinea region, but is still in need of a thorough taxonomic revision to document the exact number of species and their individual characteristics, distribution, rarity, etc.

Although the lowland rain forests of Gabon are considered to have high plant species richness, the lack of sufficient local botanical expertise forms an urgent and serious impediment for Gabon (see National CBD Action Plan <http://www.cbd.int/countries/?country=ga>). With only two botanists trained at the PhD level, Gabon is amongst the countries with the lowest amount of local expertise in tropical Africa. This is in sharp contrast with the large need for such expertise in view of the important conservation and eco-tourism developments within the country. The current study, therefore, encompasses a broad field of systematic subdisciplines, applying state of the art techniques as well as some elements that will be important tools for the proper management of Gabon's biodiversity. The Flore du Gabon series, an indispensable tool for any study of Gabonese plants, has been revitalized (Sosef and Florence 2007) and the present project will also contribute to that series. As such, the knowledge and data provided by this project will be immediately applicable within the local setting.

1.2 The science of systematics

Although the term 'biodiversity' may refer to many different aspects of the diversity of life (Heywood et al. 1995; Purvis and Hector 2000) it is generally interpreted as referring to the number of species (Lanzerath and Friile 2014). Although species represent the fundamental unit of biodiversity (Claridge et al. 1997), the definition of species is not unanimously agreed upon among biologists. Depending on the nature of the scientific approach (morphological, ecological, genetic or population studies), many species concepts have been proposed and reviewed in textbooks (Cronquist 1988; Coyne and Orr 2004; Stuessy 2009). Because our taxonomic study is mainly based on a morphological study of herbarium specimens, we adhere to the morphological species concept, that is, species being defined by macro-morphological characters or, as defined by (Cronquist 1978), the smallest groups that are consistently and persistently distinct and distinguishable by ordinary means. We think that such patterns of morphological variation are caused by the fact that each species represents a group of interbreeding natural populations that are reproductively isolated from other such group, and hence the biological species concept, which defines species as such (Mayr 1995), is also applicable. However, with no investigations on the reproductive behaviour of *Campylospermum* species, their distinction cannot be tested based on this type of species hypotheses. Sometimes, a concept of discrete species can be inadequate to deal with cryptic species or the occurrence of hybrid intermediates. Population genetics can help to define such

boundaries by revealing the genetic patterns for such problematic situations (Elmer et al. 2007; Dauby et al. 2010; Duminil et al. 2010). As such, the phylogenetic species concept, in which species are the minimal elements appropriate as terminals in a phylogenetic analysis (Davis and Goldman 1993) is considered as well.

Within the field of systematics, species are being described, named and classified in a hierarchical system reflecting the evolutionary relationships. We prefer to name only monophyletic clades, that is groups of species that include all the descendants of a single most recent common ancestor (Page and Holmes 1998), although there is a fierce debate about accepting paraphyletic clades as well (Hörandl and Stuessy 2010). While some consider the terms ‘taxonomy’ and ‘systematics’ to be synonymous, others prefer to use the term ‘taxonomy’ to refer to the process of describing, naming and classifying, while systematics would additionally enclose the phylogenetic and historical biogeographic subdisciplines. Here, we prefer the latter view and will use the term systematics to refer to the broader discipline of classification and evolution.

Systematics is a synthetic discipline, which may draw its data from a wide variety of other fields. Data can be obtained from the organism itself (Stuessy 2009) such as its morphology (Cronquist 1988; Judd et al. 2008; Takhtajan 2009), its anatomy (Gregory 1994; Evert et al. 2006; Rudall 2007), its molecular genetics (Miyamoto and Cracraft 1991; Nei and Kumar 2000; Donoghue and Smith 2004; Felsenstein 2004; Hall 2011; Lewin et al. 2014; Watson 2014), or its phytochemistry (Smith 1976; Ferguson 1980; Gottlieb 1982; Harborne and Turner 1984). Because morphological data is sometimes not easy to interpret, there has been a strong debate amongst systematists about the adequacy of morphological data as opposed to molecular data for the reconstruction of phylogenies (Karp et al. 1998). I believe, however, that the debate of ‘molecule versus morphology’ is a futile one. Molecules cannot replace taxonomy or vice versa as they simply refer to a different set of characters, both equally important. Disciplines such as biodiversity, ecology, genetic, conservation, molecular systematic and many others rely on taxonomic information to conserve, manage, share knowledge on biodiversity. At any taxonomic level, molecules, on the other hand, are used to infer organismal phylogenies. But, yet a solid taxonomic at species level is still needed. That means real people need go to the field, write up taxonomic publications (revisionary work, Flora's, checklists) and establish the synonymy in order for molecular studies to continue more in-depth studies. Even the recent developments towards DNA Barcoding (CBOL Plant Working Group 2009), needs a preliminary taxonomic framework, as well as correct identification of the material used, both based on morphology, to advance. As such, both molecule and taxonomy contribution has the same value. In conclusion, molecular and morphological data should be seen as service provider to each other and complement one another, providing different types of information to arrive at a sound and stable taxonomic framework.

1.3 Phylogeny of Ochnaceae

The usefulness of molecular approaches in analysing phylogenetic relationships at higher rank is eminent. During the past decades, it has led to the change of existing classifications into more natural ones (APG III 2009; Chase and Reveal 2009). The large clade of the Rosids provides a nice example of such changes, demonstrated by numerous studies (Chase et al. 1993; Doyle et al. 1994; Soltis et al. 1997; Nandi et al. 1998; Qiu et al. 1999; Savolainen, Chase, et al. 2000; Savolainen, Fay, et al. 2000; APG III 2009; Chase and Reveal 2009). In Rosids, further changes are ongoing because some phylogenetic relationships are still unresolved, or the monophyly of some clades is still not well supported. Such is also the case within the Rosid order Malpighiales, one of the largest orders of the flowering plants (Wurdack and Davis 2009; Xi et al. 2012), and which includes the Ochnaceae. The order contains about 40 families and more than 16,000 species (Wurdack and Davis 2009; Endress et al. 2013). The current composition of the Malpighiales was first identified by Chase et al. (1993), based on *rbcL* gene sequence data of 499 species of seed plants. Based on the fact that no single gene sequence can provide reliable relationships, additional molecular phylogenetic studies were performed. More data (molecular as well as morphological) and taxa were added (Chase et al. 1993; Nandi et al. 1998; Qiu 1999; Savolainen, Chase, et al. 2000; Savolainen, Fay, et al. 2000; Soltis et al. 2000) to improve the resolution of poorly supported clades within Angiosperms, such as the Malpighiales. Phylogenetic studies on Malpighiales inferred from plastid, mitochondrial and nuclear markers have now provided support for the monophyly of the order and many of its component families (Davis et al. 2005; Korotkova et al. 2009; Wurdack and Davis 2009). Recent attempts using phylogenomic approaches have made significant progress (Xi et al. 2012), while comparative studies of the floral structures, pollen and tapetal evolution, provide a firm phylogenetic foundation (Matthews et al. 2012; Endress et al. 2013; Furness 2013). Nevertheless, within the Malpighiales, some relationships remain unresolved (Wurdack and Davis 2009; Xi et al. 2012), such as the phylogenetic position of the Ochnaceae.

Until about 15 years ago, not much attention had been paid to the question about the systematic position of the Ochnaceae. Apparently, taxonomists were more interested in the taxonomic division within this family. Nevertheless, based on seed and ovule characters, Van Tieghem (1902b, c) suggested two possible phylogenetic positions for the family: either within the order Oxalidales or within the Clusiaceae. Studies based on gene sequence data now place Ochnaceae as sister to the Medusagynaceae (a monotypic family from the Seychelles) and the Quiinaceae (from tropical America) (Fay et al. 1997; Davis et al. 2005; Schneider et al. 2006; Korotkova et al. 2009; Bell et al. 2010; Soltis et al. 2011). The APG classification (APG III 2009) unites the three families to form an expanded Ochnaceae s.l. which sits in a clade together with the

Clusiaceae, Bonneticaceae, Hypericaceae, Calophyllaceae and, surprisingly, the weird Podostemaceae. Indeed, Podostemaceae is an aquatic herb occurring only in rapids. Its highly modified morphology is so different from any other angiosperms (Ueda et al. 1997).

Recently, the phylogeny of Ochnaceae has been analysed in more detail (Schneider et al. 2014). This is the first comprehensive molecular phylogeny of Ochnaceae inferred from combined plastid loci (*matK*, *ndhF*, *rbcL*, *trnLF*) and nuclear ribosomal DNA (ITS1, 5.8S, ITS2). The study confirmed the monophyly of the clade uniting the three families and preferred to maintain the APG classification of an expanded Ochnaceae s.l (from now on referred to as Ochnaceae), which consists of three subfamilies: Medusagynoideae Reveal, Quiinoideae Luerss. and Ochnoideae Burnett. This updated classification brings more stability and the three subfamilies do form distinct monophyletic clades and are morphologically well-characterized (Wurdack and Davis 2009; Matthews et al. 2012; Xi et al. 2012; Endress et al. 2013).

The phylogeny of Quiinoideae has been studied (Schneider et al. 2002; Schneider et al. 2006) and includes four genera: *Froesia* Pires, *Lacunaria* Ducke, *Quiina* Aubl. and *Touroulia* Aubl., with *Froesia* being sister to the rest of Quiinaceae.

Ochnoideae is by far the largest subfamily of Ochnaceae and has now been subdivided into four tribes: Testuleeae Schneider, Luxemburgiae Horan., Sauvagesieae Ging. ex DC. and Ochneae Bartl.. The latter is, in turn, is divided into three subtribes (Elvasiinae Schneider, Lophirinae Schneider and Ochninae Kanis ex Schneider). The family has about 500 species in 27 genera (Amaral 1991; Amaral and Bittrich 2014). The Neotropical region comprises the largest number of species: some 300–350 in 15 genera. In Africa, including Madagascar, about 150 species and 9 genera occur (Perrier de la Bâthie 1951; Verdcourt, 2005 #7). The lowest diversity is observed in South-East Asia, hosting 20 species and 8 genera (Kanis 1968; Verdcourt 2005). Potential synapomorphies uniting the Ochnaceae are listed by Matthews et al. (2012) and Endress et al. (2013). The family is also distinguished by having densely spaced parallel secondary veins and the tertiary veins perpendicular to these (Amaral and Bittrich 2014). Flowers are actinomorphic or zygomorphic, basically pentamerous but the number of sepals, petals and stamens is not constant within the family (Matthews et al. 2012; Amaral and Bittrich 2014). Several genera have winged seeds, which are probably wind-dispersed (Amaral and Bittrich 2014), while fruits of others, notably those in the subtribe Ochninae, seem to be adapted to bird dispersal. In Ochnaceae, it is common to encounter adaptations for buzz-pollination (bees or bumblebees are able to grab onto the flower and move their flight muscles rapidly, causing the flower and anthers to vibrate, dislodging pollen), notably those with long, apically poricidal anthers (Kubitzki and Amaral 1991; Nadia and Machado 2005; Matthews et al. 2012).

The objective of our phylogenetic study is to:

- **reconstruct the phylogenetic history of the Ochnaceae family inferred from matK, rbcL and trnL-F, with special emphasis on the Old World genus Campylospermum;**

1.4 Historical biogeography of Ochnaceae

Ochnaceae is a family of trees, shrubs or rarely herbs (*Sauvagesia* L.). They are widely distributed in tropical and subtropical forests and savannas of the Old and New World.

The Neotropical Ochnaceae are distributed from Central to South America. Central America is poor in species, whereas a high level of endemic species, mainly within the genus *Ouratea*, is observed in the northern part of South America (Sastre 1987). The palaeotropical Ochnaceae are mostly found in the tropical regions of West, Central, East and South Africa (not in the southern part of South Africa where a Mediterranean climate prevails), while few species occur in Madagascar and associated islands (Seychelles and Mascarenes) as well as in the Indo-Pacific region and South-East Asia. A central question is: "How did Ochnaceae acquire their present-day disjunct distribution across all main tropical areas?"

We can distinguish two categories of relevant routes that were potentially used for the migration of plants in the past (Morley 2003). The first comprises routes related to the Gondwana break-up (late Cretaceous, early Tertiary) while the second relates to phases of plate collision (middle Eocene). Plant migration from South to North America might have been possible through different land-connections at different periods of time. Such a land-connection could have been the proto Greater Antilles (50 Ma) or Gaarlandia present during the Eocene-Oligocene (Graham 2003a; Ali 2012). In the early Tertiary, dispersal from northern America and Europe may have been possible via the North Atlantic Land Bridge (NALB). From the early Palaeogene to the late Miocene/early Pliocene, while the Bering Land Bridge (BLB) may have allowed migration from North America to Asia. These land-connections may have been available to many angiosperm plants that now show disjunct distributions between the tropics of South America, Africa and Southeast Asia, e.g. Annonaceae and Rhamnaceae (Richardson et al. 2004), Malpighiaceae (Davis et al. 2002), Lauraceae (Chanderbali et al. 2001) Campanulaceae and Rubiaceae (Antonelli et al. 2009). Here, we want to establish which path (or paths) the Ochnaceae took to move between continents.

To date, the historical biogeography of Ochnaceae has never been subject of a detailed study, mainly because a comprehensive molecular phylogenetic hypothesis was lacking. Although the Ochnaceae have originated in the late Cretaceous (Davis, et al. 2005; Xi, et al. 2012), the geographic origin of the family is still uncertain. Moreover, the position

of Ochnaceae within Malpighiales has been unclear until recently, when Xi et al. (2012) inferred that they are sister to the Clusioid clade, though with low support (Bayesian posterior probability = 0.81). Furthermore, looking at their phylogenetic tree, the branch between the stem node and crown node of the Ochnaceae reflects some 30 million years of non-traceable divergences. Because of this, it is difficult to reconstruct the biogeographic history of the family (especially the ancestral area of the crown node) with confidence. Nevertheless, the phylogeny produced within this study will be used to:

- **reconstruct the biogeographic history of the Ochnaceae family, with a special focus on the assessment of its area of origin;**
- **estimate divergence times of Ochnaceae lineages, with a special focus on the disjunctions between the Neotropical and Palaeotropical Ochnaceae lineages.**

1.5 Systematics of *Campylospermum*

Species of the genus *Campylospermum* Tiegh. are treelets with various architecture sensu Hallé et al. (1978) and occur in the African and Asian tropics. Within Africa, *Campylospermum* occurs from Senegal to Angola in the West and from Ethiopia to Madagascar in the East (Farron 1985). In Asia, the distribution extends into eastern China and the Malesian region (Kanis 1968). It belongs to the subfamily *Ochnoideae*, tribe *Ochneae*, subtribe *Ochninae* (Schneider et al. submitted). This subtribe contains five other genera: *Brackenridgea* A.Gray, *Idertia* Farron, *Ochna* L., *Ouratea* Aubl. and *Rhabdophyllum* Tiegh. *Brackenridgea* and *Ochna* were formerly placed into the subtribe *Ochninae* and the rest into *Ourateinae* (Farron 1963; Kanis 1968; Farron 1985; Sastre 1988; Sosef 2008, 2013). They are characterized by having a five-parted perianth, a gynobasic style, almost free carpels that are post-genitally fused, and a receptacle that becomes reddish and swollen in fruit (Schneider et al. submitted). While *Brackenridgea* and *Ochna* generally have numerous anthers, the other genera have ten.

Because flowers of *Campylospermum* are fairly uniform, characteristics of the leaf shape and venation, as well as the inflorescence structure have often been used to distinguish the species. This has led to a situation where the species are sometimes difficult to tell apart by a non-specialist. Farron (1965, 1985) worked intensively on the continental African *Campylospermum* species and subdivided the genus into six sections. His sectional subdivision was heavily based on the shape and position of the embryo and its cotyledons. Section *Bisetaria* Tiegh. included a single species, *Cercanthemum* Tiegh. three species, *Campylospermum* six species, *Diphyllodium* Tiegh. three species, *Notocampylum* Tiegh. eight species and *Monelasmum* Tiegh. 15 species. To date, the total number of species lies close to 50 (Bissiengou et al. 2013).

The African *Campylospermum* have never been fully revised, although Farron (1963, 1965, 1968, 1985) and others (Robson 1963; Bamps and Farron 1967; Verdcourt 2005) published useful parts for such a revisionary work, at least of the continental species. Perrier de la Bâthie (1951) treated five *Campylospermum* species known from Madagascar. This number will almost certainly increase with new species that are not yet described but already stored in herbaria, which act as the major facilities for species discovery (Bebber et al. 2010). Farron (1985) established an identification key as well as the geographical distribution of each of the continental African species, but he never published full species descriptions, apart from the sixteen species treated in the *Flore d'Afrique centrale* (Bamps and Farron 1967). In his identification key, species are not keyed out according to their sectional arrangement. Furthermore, the list of accepted names and synonymy that he published in 1965 is, unfortunately, incomplete, which leaves us with several names of uncertain status. The phylogeny of the genus *Campylospermum* has never been studied, rendering the intrageneric classification proposed by Farron uncertain. Besides that, some doubts have arisen concerning the monophyly of the genus and its distinction with the genera *Idertia*, *Rhabdophyllum* and *Ouratea*. The objective of our study on the genus *Campylospermum* is to:

- **undertake a full taxonomic revision of the continental African species of *Campylospermum*, including a user-friendly identification key;**
- **assess the IUCN conservation status of each *Campylospermum* species;**
- **assess whether or not the genus comprises a monophyletic group;**
- **assess the phylogenetic relationships within the genus, and its taxonomic consequences for the sectional arrangement.**

1.6 Methodologies used in this study

1.6.1 Taxonomic part

Herbarium and library

The study starts with a thorough literature study, aiming to identify all publications that have ever been published concerning *Campylospermum*. This is done in order to identify all taxon names formerly published in the literature and to compile a definitive list of species names that need to be treated in this study. Furthermore, all data related to herbarium specimens (at least for those species occurring in continental Africa) are compiled using the BRAHMS database of the National Herbarium of the Netherlands, supplemented with electronic data obtained through the GBIF portal (<http://www.gbif.org/>) and the Aluka African Plant Initiative Database (<http://www.aluka.org/page/content/plants.jsp>). This is done in order to assess the location of all type specimens and to choose from which herbaria material should be asked on loan. Visits were realized to

herbaria such as BM, BR, K, and P that keep important collections of *Campylospermum*, in order to study their material. In all, over 4500 herbarium specimens are incorporated in this study.

Field work

Field trips in Gabon and Cameroon yielded additional morphological observations not available from herbarium material of the *Campylospermum* species. Additionally, an attempt was made to make observations on pollination, phenology (flowering and fruiting periods) and seed dispersal, on which still no data existed.

During the field trips, 257 herbarium specimens were collected, representing 26 species, that is, more than 90% of the species occurring in both countries.

IUCN conservation status

Despite all these efforts, our knowledge about some of the African *Campylospermum* species is still limited. Some are known from only one or two flowering collections, others seem to have a very restricted distribution area. Several species new to science have been discovered and described. In order to contribute to their conservation, a preliminary assessment for an IUCN conservation status (Red Data List) of each species was realized. Gabon has reserved more than 10% of its surface for conservation purposes, while Cameroun is close to doing the same. Such data is thus most welcome for park management and priority settings.

1.6.2 Phylogenetic part

Taxon sampling

Fresh DNA material was collected in the field especially from species in the genera *Campylospermum*, *Idertia*, *Lophira*, *Ochna*, *Rhabdophyllum*, *Sauvagesia* and *Testulea*. Species not encountered in the wild were sampled from herbarium material. Our final taxon sampling (Chapter 4 and 5) of Ochnaceae comprises all genera, except *Indosinia* J.E.Vidal which could not be obtained from herbarium nor from a silica sample.

Character sampling

Sequence data for *matK*, *rbcL* and *trnL-trnF* (including the *trnL* intron, *trnL* 3' exon and *trn-LtrnF* intergenic spacer) are produced. For many taxa only herbarium material was available, which often yielded low quality DNA. Amplification and sequencing of samples from herbarium specimens often fails due to the highly degraded nature of the DNA (Särkinen et al. 2012). Because of that, sequences of some taxa contain a high amount of missing data. However, it has been shown that the accuracy of phylogenetic analyses is robust as to the inclusion of incomplete taxa, even when the amount of missing data is substantial (Cho et al. 2011; Wiens and Morrill 2011). Therefore, taxa with incomplete

sequence data from all currently recognised subfamilies (Medusagynoideae, Quiinoideae and Ochnoideae) were included in our data set. In some cases, complete sampling of terminal taxa was obtained by sampling sequences from different individuals of the same species (Campbell and Lapointe 2009), thus creating composite terminal taxa.

Phylogenetic inference

The methods used to infer phylogenetic trees were Maximum Parsimony (MP), Maximum Likelihood (ML) and Bayesian inference. MP is a non-parametric method whereas the other two are model-based. MP searches for the tree topology which relates to the minimal amount of character state changes (in DNA sequence data these are actually nucleotide substitutions), assuming such a tree needs the lowest amount of ad-hoc hypotheses and hence is our best estimate of the actual phylogeny (Page and Holmes 1998). However, it is also possible to represent state changes via models of DNA sequence evolution. Many such model-based methods of tree inference were reviewed by Felsenstein (2004). Of these methods, ML and Bayesian phylogeny inference both use likelihood function, which provides the probability that the tree has given rise to the data observed. Bootstrap values are used to indicate supports of clades in the phylogenetic tree. To reconstruct the phylogeny of Ochnaceae, we used coding and non-coding gene regions that have different underlying evolutionary histories. To make sure that support of clade relationships depicted in the phylogenetic tree are consistent with the evolutionary histories of both types of gene regions, bayesian inferences are applied. In Bayesian inferences, parameters are allowed to vary randomly within the limits of a pre-defined parameter space, or prior distribution. This prior probability, combined with likelihood functions, provides the posterior probability distribution, which is the basis of Bayesian inference.

1.6.3 Molecular dating

Divergence times

Since any dating analysis will ultimately depend on the quality of branch length estimations, likelihood and Bayesian analyses are generally preferred over parsimony methods. Subsequently, the phylogenetic tree was tested for clock-like accumulation of the nucleotide substitutions using the software BEAST (Drummond and Rambaut 2007). BEAST is a cross-platform programme for Bayesian MCMC analysis of molecular sequences. It is entirely orientated towards rooted, time-measured phylogenies inferred using strict or relaxed molecular clock models (Drummond and Rambaut 2007). BEAST has the advantage of being flexible when defining parameters of an evolutionary model. Our dataset comprises coding and non-coding aligned DNA sequences. BEAST analyses allows us to define a different substitution rate for each partition, resulting in a different amount of rate heterogeneity among sites. In fact, any or all parameters (including

the tree itself) can be shared or independent among partitions of the sequence data (Drummond and Rambaut 2007).

Ochnaceae fossil records being unknown, secondary calibration is used under the relaxed molecular clock models.

Ancestral area reconstruction

To infer biogeographic histories, model and event-based approaches are available but each of them does have their own limitations. For instance, Dispersal-Vicariance Analysis (DIVA) (Ronquist 1997; Ronquist 2001) is one of the most widely used methods for inferring biogeographic histories, but its current implementation raises two issues. First, it ignores the uncertainty in phylogenetic inference because ancestral ranges are reconstructed onto a fixed tree topology, which is assumed to be without error (J. A. A. Nylander et al. 2008). A second issue is that multiple equally optimal reconstructions often result in multiple ranges suggested at ancestral nodes (Ronquist 1997; J. A. A. Nylander et al. 2008). To deal with these uncertainties, Nylander et al. (2008) showed the utility of a non-parametric empirical Bayesian approach to DIVA. Their approach handles phylogenetic uncertainty and uncertainty in DIVA optimization. Yu et al. (2010) proposed Statistical Dispersal-Vicariance Analysis (S-DIVA), a programme which complements DIVA and determines statistical support for ancestral range reconstructions using a novel method, the S-DIVA value. The Reconstruct Ancestral State in Phylogenies (RASP) software developed by Yu et al. (2013) is another useful tool for biogeographic inference. It implements three methods, S-DIVA, Bayesian binary MCMC (BBM) and Maximum Parsimony (MP) analysis. In S-DIVA, the frequencies of an ancestral range at a node in ancestral reconstructions are averaged over all trees and each alternative ancestral range at a node is weighted by the frequency of the node occurring or by some other measure of support (posterior probabilities) for the node Yu et al. (2010). In this study, the RASP software was used to test which path (or paths) Ochnaceae took to move between continents.

1.7 The study outline

The goal of this study was to investigate the evolution and historical biogeographic scenarios of the family Ochnaceae, with a special focus on the African genus *Campylospermum* for which a taxonomic revision needed to be prepared first. The current study is divided into two major parts, viz, (1) Taxonomy and (2) Phylogenetics and Biogeography. Data concerning these two parts have been gathered from the study of living (field) and conserved (herbarium specimens) material. To clarify the taxonomy of the genus *Campylospermum* more than 4500 specimens have been carefully studied. The necessary formal description of new species and new combinations are presented

in Chapter 2. In Chapter 3, we present a full taxonomic revision of the continental African species of *Campylospermum* which provides the key diagnostic characters for each of them. One of the practical applications of this chapter is the establishment of an identification key for all continental African species. A preliminary assessment of the IUCN conservation status of each species is included for park management and priority settings.

The phylogeny of the family Ochnaceae has been recently studied based on combined chloroplast and nuclear gene regions. Chapter 5 provides the results of a much more extended study, including DNA sequence data from eastern African and Malagasy species of *Campylospermum*. This phylogeny is based on a data set comprising three chloroplast markers (*matK*, *rbcL*, *trnLF*). Together with information on geography and fossils, as well as two additional markers, *ITS* and *ndhF*, chapter 5 provides a framework for hypotheses on the vicariance and dispersal events that have led to the distribution of extant Ochnaceae species.

Chapter 2

Taxonomic novelties in the genus *Campylospermum* (Ochnaceae)

Published in *Blumea* 2013, 58:1-7

Abstract

Four new species, one with two subspecies, of the genus *Campylospermum* are described, all endemic or sub-endemic to Gabon. These are *C. auriculatum*, *C. gabonensis*, *C. gabonensis* subsp. *australis*, *C. glaucifolium* and *C. occidentalis*. Distribution maps and scans of the holotypes are provided as well as preliminary IUCN Red List assessments. New combinations for nine species formerly assigned to the genus *Ouratea* and/or *Gomphia* are proposed: *C. andongensis*, *C. glomeratum*, *C. longestipulatum*, *C. lunzuensis*, *C. lutambensis*, *C. nutans*, *C. plicatum* and *C. warneckeii*. Finally, one taxon is raised from the variety to species level, leading to the new combination *C. costatum*.

Keywords: Africa, *Campylospermum*, conservation, Gabon, *Gomphia*, IUCN Red List, *Ochnaceae*, *Ouratea*, Taxonomy

2.1 Introduction

The genus *Campylospermum* has about 50 species occurring in continental Africa, Madagascar, extending east to China and the Malesian region. It belongs to the subfamily *Ochnoideae*, tribe *Ochnaeae*, subtribe *Ouratinae* (Kanis 1968). This subtribe contains three other genera: *Rhabdophyllum* Tiegh. (Africa, 8 species), *Ouratea* Aubl. (Neotropics, c. 140 species) and *Idertia* Farron (Africa, 3 species; Farron 1985, Kanis 1968, Sastre 1988, Sosef 2008). In contrast to *Ochnaceae* specialists who recognized these genera as being distinct, generalists more often preferred a broader genus concept in which *Oura-tea* comprises the genera *Campylospermum* and *Idertia* (e.g. Hutchinson et al. 1954), and sometimes even *Rhabdophyllum* (e.g. Aké Assi & Gautier 2000, Verdcourt 2005).

The new species published here are part of our on-going research efforts on the systematics of *Ouratinae* in cooperation with the Senckenberg Research Institute at Frankfurt. *Rhabdophyllum* was revised recently (Sosef), but notably the taxonomy of *Campylospermum* is still unclear. The first author is preparing her PhD thesis on the taxonomy, phylogeny and biogeography of *Ochnaceae*, with an emphasis on *Campylospermum*. Most of the novelties resulting from her taxonomic work on the continental African representatives are presented here. Molecular phylogenetic work in progress (Bissiengou, unpubl. data) has not yet led to sufficient resolution in the phylogenetic tree and hence does not yet allow resolving the relationships among the four *Ouratinae* genera. Being unable to anticipate future phylogenetic results, for now we adopt a conservative approach and adhere to generic concepts based on morphology.

The generic name *Gomphia* Schreb. [1789] is to be regarded as a synonym of the older *Ouratea* Aubl. [1775], following a complex lectotypification (Kanis 1967, Bittrich & Amaral 1994). Unfortunately, the latter publication was apparently missed by Verdcourt (2005), who followed Kanis (1967) and thus erroneously re-introduced the genus name *Gomphia* in African botanical literature.

Tropical African *Ochnaceae* have been treated in various Flora's (Bamps & Farron 1967, Hutchinson et al. 1954, Robson 1963, Verdcourt 2005). However, species occurring in the Lower Guinean area (part of the Guineo-Congolian floristic region, or phytocorion; White 1979) remain without a proper taxonomic treatment to date. Although Farron (1965, 1968, 1985) published important contributions to the taxonomy of African *Ouratinae*, relevant for this area, our knowledge about this group remains highly incomplete. This information gap is seen in many other plant groups and is especially relevant in the light of the fact that the lowland rain forests of the Lower Guinean region (notably those in Cameroon and Gabon) are regarded as the most species-rich of tropical Africa (Mutke et al. 2001, Linder 2001, Küper et al. 2004, Sosef et al. 2006, Estrella de la et al. 2012, Linder et al. 2012). For this area, taxonomic revisions are indispensable, since in some cases they directly contribute to datasets that help prioritize conservation efforts (e.g. Burgess et al. 2005). The Flore du Gabon production tries to address the knowledge gap (Sosef & Florence 2007), but its existence as

well as the extraordinary species richness of Lower Guinea is further emphasized by the fact that all species in African *Oura-tinae* that have been described during the past 25 years (e.g. Sosef et al. 2007, Bissiengou & Sosef 2008, this publication) are endemic or sub-endemic to Gabon. Along with the fact that the botanical exploration of Gabon is far from complete (Sosef et al. 2006), this means that still many other novelties may be expected to emerge from Gabon's lush vegetation (see for example Walters et al. 2011).

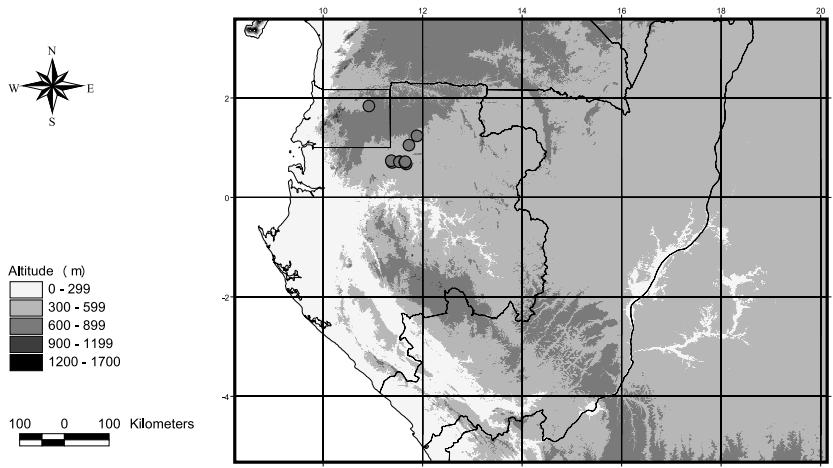

2.2 Materials and Methods

To perform the taxonomic revision of the genus *Campylospermum*, herbarium material from the following herbaria has been consulted (acronyms follow Thiers 2012): A, B, BAS, BM, BR, BRLU, C, COI, E, EA, FHO, G, K, L, LBV, LISU, LY, MA, MO, NEU, P, PRE, S, SRGH, US, WAG, Z.

All specimen data have been entered into the BRAHMS (Botanical Research and Herbarium Management System) database of the National Herbarium of the Netherlands (now part of the Naturalis Biodiversity Center). To perform an assessment of the IUCN category of threat for each taxon, the BRAHMS software was used in combination with ArcView 3.3 and the IUCN Red List add-in script developed by Moat (2007). Assignments follow the IUCN guidelines (IUCN Standards and Petitions Subcommittee 2011), but not the advice to set the cell width/height to 2 km. Instead, a sliding scale grid cell width is applied, which is deemed more appropriate for herbarium record data (Moat 2007). We define a 'location' as a single grid cell. All assignments will be sent to IUCN for approval in the near future, which is why we characterize them as 'preliminary' for now.

2.3 New Taxa

Campylospermum auriculatum Biss., sp. nov. — Fig. 1; Map 1

Map 1. Distribution of *C. auriculatum* Biss.

Diagnosis: This species resembles *C. schoenleinianum* (Klotzsch) Farron because of its auriculate to deeply cordate leaf base, but differs by the leaf blade being broader in the basal part, and by having caducous stipules, a serrate leaf margin, a flattened peduncle and shorter and more compact racemes of 3–11 cm long.

Type: *Strijk* 73 (holo WAG; iso LBV), Gabon, Woleu-Ntem, Bordamur con-cession area, some 40 km from WWF-station, N1°14', E11°53', 10 Oct. 2002.

Understorey treelet up to 6 m tall. *Stipules* caducous, 3–5 mm long. *Leaves*: petiole 0–2 mm long; leaf blade elliptic-obovate to oblanceolate, (9–)14–24(–31) by (4–)6–8(–11) cm, base auriculate to deeply cordate, often clasping the twig, apex acute, coriaceous to thick leathery, margin serrate, upper surface glossy green, lower surface dull paler green; midrib flattened above, prominent below, main lateral veins 10–20 mm apart, 16–19 on either side, curved upward to run parallel to the margin, intermediate lateral veins prominent on both sides, 0–2 in between each pair of main laterals, tertiary venation scalariform, very distinct on both sides. *Inflorescences* terminal or rarely axillary, its main axis 12–15(–18) cm long, flattened; racemes 1–6, 3–9(–11) cm long; pairwise scales absent; bracts persistent at the base of the raceme and pedicel, triangular, c. 3–5 mm long; cymules 5–9 mm apart, 2–4(–6)-flowered. *Flowers*: pedicel 5–7 mm, articulated at 2–3 mm from the base; sepals 5, ovate, in flower 7–8 by 2–3 mm, yellowish green, in fruit persistent and accrescent, 9–10 by 3–4 mm, bright red; petals 5, obovate, 7–12 by 3–4 mm, cuneate at base, rounded at apex, bright yellow; stamens 10, caducous, orange-yellow, filaments less than 1 mm long, anthers 3–4 mm long, transversely wrinkled, poricidal; ovary c. 2 mm wide; style c. 4 mm long, curved, yellow. *Fruits*: receptacle a ± flattened-globose shape, c. 5 mm wide, orange-red; drupelets 1–3 well developed per receptacle, reniform, c. 8 by 5 mm, black at maturity; cotyledons incumbent, dissimilar in size with a small outer cotyledon.

Distribution: Equatorial Guinea (Rio Muni) and Gabon (Woleu-Ntem province).

Ecology: In primary or secondary forest; on brown clay soil; at 475–600 m altitude.

Phenology: Flowers and mature fruits collected from October to November, flowers also observed in April, which coincides with the two rainy seasons.

Preliminary IUCN conservation status: VU B1/B2ab(ii, iii, iv). EOO = 6098 km², AOO = 1653 km², locations = 7 (cell width = 15.37 km). All collections have been made recently (the oldest one is from 1983). The only collection from Equatorial Guinea is from within a protected area (Inselberg at Akuom). The other ten collections from Gabon are from a fairly restricted area where logging companies operate which may lead to a decline in the AOO and/or extent of suitable habitat and hence we propose the 'Vulnerable' category.

Additional material: EQUATORIAL GUINEA, Rio Muni, Wele Nzas: *Parmentier* 358 (BRLU), Inselberg d'Akuom, à 1h30 de marche (6 km) du village de Nzuameyong, à 25 km d'Anisoc, N1°50' E10°55', 600 m, 13 June 1999 (st).-GABON, Woleu-Ntem: *Bissiengou* 667 (LBV, WAG), c. 8 km SSW of Mitzic, FOREENEX forest exploitation, N0°42.9' E11°32.0', 547 m, 6 Nov. 2009 (fr); *Bissiengou* 707 (LBV, WAG), 8.5 km SSW of Mitzic, FOREENEX forest exploitation, N0°42.5' E11°31.9', 501 m, 6 Nov. 2009 (fl); *Bissiengou* 714 (LBV, WAG), 13 km SE of Mitzic, FOREENEX forest exploitation, road from forestry camp to Madouaka village, N0°42.4' E11°38.2', 480 m, 7 Nov. 2009 (fl); *Bissiengou* 730 (LBV, WAG), 13 km SE of Mitzic, FOREENEX forest exploitation, road from forestry camp to Madouaka village, N0°42.1' E11°38.8', 490 m, 7 Nov. 2009 (fr); *Bissiengou* 769 (LBV, WAG), 35 km NNE of Mitzic, forestry road in Bordamur forest exploitation, 2 km from forestry camp, N1°02.8' E11°43.3', 545 m, 8 Nov. 2009 (st); *Breteler* 8797 (LBV, WAG), 30–40 km NE of Saint Germain, E of Okano River, c. N0°40' E11°40', 475 m, 18 Apr. 1988 (fl, fr); *A.M. Louis* 377 (K, LBV, WAG), Oveng, 65 km N of road Benguié-Lalara, forest exploitation camp, N0°42' E11°23', 500 m, 5 Nov. 1983 (fl, fr); *Maas* 10052 (LBV, WAG), RN 2, S of Mitzic, FOREENEX-concession, N0°42.8' E11°38.9', 503 m, 30 Oct. 2011 (fl); *Reitsma* 2493 (WAG), Inventory Oveng, c. 25 km WSW of Mitzic, N0°44' E11°22', 6 Nov. 1986 (fl, fr).

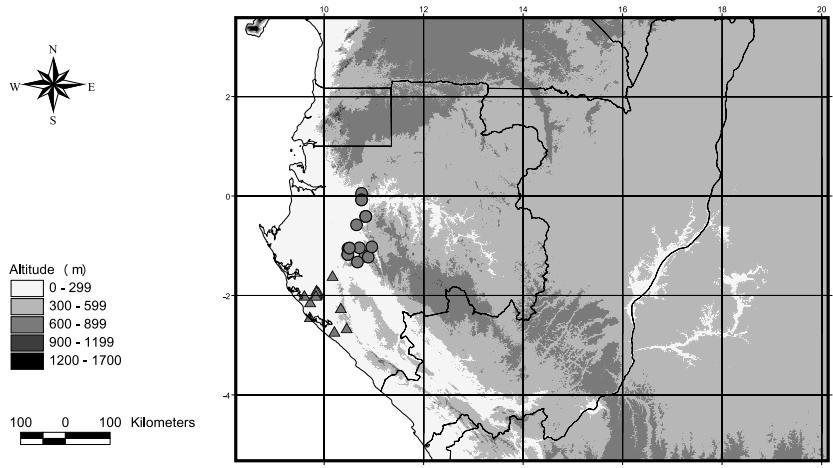

Note : Especially the auriculate to deeply cordate leaf base is highly reminiscent of *C. schoenleinianum*, a species confined to western tropical Africa (from Guinea to Ghana).

Campylospermum gabonensis Biss., sp. nov.

Diagnosis: A species resembling *C. claessensii* (De Wild.) Farron, but with persistent, 7–15 mm long, stipules and an un-branched and compact inflorescence.

Type: *Breteler & Breteler-Klein Breteler* 13124 (holo WAG; iso LBV, WAG), Gabon, Moyen-Ogooué, c. 20–30 km NNW of Ndjolé, N0°03' E10°45', 2 Oct. 1994.

⇒ *subsp. gabonensis* — Fig. 3; Map 2

Map 2. Distribution of *C. gabonensis* Biss. subsp. *gabonensis* (dots) and subsp. *australis* Biss. (triangles).

Tree or treelet, up to 7 m tall. *Stipules* persistent, narrowly triangular, 7–15 cm long. *Leaves*: petiole canaliculated above, 3–7 mm long; leaf blade narrowly elliptic to narrowly elliptic-obovate, 16–30(–35) by 6–10(–11) cm, base cuneate to tapering, apex acuminate or sometimes acute, thick leathery to coriaceous, margin serrulate or sometimes entire toward the base, rarely entire, upper surface flat or rarely bullate, dark green, lower surface paler green, both sides glossy, young leaves purple-red; midrib flattened above, prominent below, main lateral veins 6–23 mm apart, 14–27 on either side, prominent on both sides, curved upward to run parallel to the margin, intermediate lateral veins not to slightly prominent on both sides, 0–2 in between each pair of main laterals, tertiary venation scalariform, running perpendicular to the midrib, indistinct on the upper side, slightly distinct on the lower. *Inflorescences* terminal, unbranched, erect, compact, 3–13 cm long; peduncle robust; pairwise scales persistent at the base of the peduncle, narrowly triangular; bracts persistent at the base of the cymule, triangular, 2–3 mm long; cymules 3–5(–10) mm apart, 4–8-flowered. *Flowers*: pedicel 5–15 mm, articulated at 3–9 mm from the base, pale green; sepals 5, ovate, in flower 7–9 by 2–3 mm, greenish, in fruit 9–10 by 3–4 mm, persistent and accrescent, red; petals 5, obovate, yellow, 10–15 by 5–9 mm, cuneate at base, rounded at apex; stamens 10, pale yellow, filaments less than 1 mm long, anthers 5–7 mm long, transversely wrinkled, poricidal; ovary c. 2 mm wide; style 6–7 mm long, curved. *Fruits*: receptacle a ± flattened-globose shape, 3–4 mm wide, red; drupelets 1–2 well developed per receptacle, ellipsoid, c. 7 by 5 mm, black at maturity; cotyledons incumbent, dissimilar in size with a smaller outer cotyledon.

Distribution: Endemic to Gabon (Moyen-Ogooué and Ngounié provinces).

Ecology: In primary and secondary forest, sometimes along rivers or streams; at 70–400 m altitude.

Phenology: Flowers observed from August to November and in April; fruits collected from October to January.

Preliminary IUCN conservation status: VU B1ab(ii, iii, iv). EOO = 4476 km², AOO = 2348 km², locations = 10 (cell width = 15.32 km). All known records of this taxon are from areas exposed to mining and/or logging activities rendering a projected decline in its AOO and/or quality of the habitat most likely and hence we propose the ‘Vulnerable’ category.

⇒ subsp. *australis* Biss., subsp. nov. — Fig. 4; Map 2

IUCN conservation status: VU B1/B2ab(ii, iii, iv). EOO = 6862 km², AOO = 1545 km², locations = 10 (cell width = 12.43 km). This taxon is known only from 15 recent collections, five of which fall within the Loango National Park and the Moukalaba-Doudou National Park. The remaining ten collections originate from logging and oil concessions while even the Loango park is under development threat from Chinese mining companies. Therefore this subspecies is best placed in the category ‘Vulnerable’.

Diagnosis: Like the typical subspecies, but the leaf blade bullate between the lateral veins or rarely flat and the scalariform tertiary veins running perpendicular to the main lateral veins.

Type: Wieringa 2852 (holo WAG; iso BR, LBV, MO), Gabon, Ogooué-Maritime, Rabi, 0.6 km on the road to platform Rabi 78, S $1^{\circ}55.1'$, E $9^{\circ}50.8'$, 4 Oct. 1994.

Distribution: Endemic to Gabon (Ogooué-Maritime, western Ngounié and Nyanga provinces).

Ecology: In primary, moist and wet forest, in valleys with small streams; on sandy soil; at 3–350 m altitude.

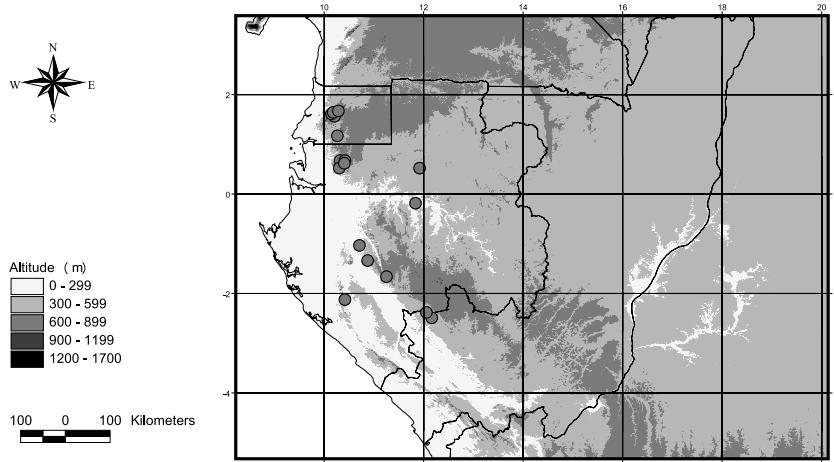

Phenology — Flowers observed from October to December; fruits collected from October to January.

Notes: This subspecies can be added to the list of taxa endemic to the greater Loango-Rabi area (Wieringa & Mackinder 2012). It is also an addition to the recently published checklist of Loango National Park (Harris et al. 2012), and provides further evidence for the unique vegetation in this part of Gabon (Wieringa & Sosef 2011). Apart from the fact that the material shows a scalariform venation different from that of the typical subspecies, and a tendency to have more obviously bullate leaves, there seem to be no other differentiating characters. This, together with the parapatric distribution of the two entities, made us decide to distinguish the taxon at the subspecies level.

***Campylospermum glaucifolium* Biss., sp. nov. — Fig. 5; Map 3****Map 3.** Distribution of *C. glaucifolium* Biss.

Diagnosis: A species resembling *C. calanthum* (Gilg) Farron, but with a glaucous upper leaf surface (at least when dry), longer petiole, and a pendulous inflorescence that carries 0–2(–3) racemes.

Type: J.J. de Wilde et al. 10165 (holo WAG; iso LBV), Gabon, Estuaire, 1 km W of Nkan, along the road from Assok to Méla, N $0^{\circ}40'$, E $10^{\circ}19'$; 23 Jan. 1991.

Treelet up to 2 m tall. *Stipules* caducous, 2–3 mm long. *Leaves*: petiole 7–15(–20) mm long, canaliculate above; leaf blade narrowly elliptic to narrowly elliptic-obovate, 13–25(–30) by 4–7(–8) cm, base cuneate, apex acuminate, leathery to coriaceous, margin serrulate, upper surface glossy, dark green but turning glaucous when dry, lower surface pale green, young leaves reddish; midrib generally prominent on both sides, main lateral veins 10–15 mm apart, 14–16 on either side, slightly prominent above, prominent below, curved upward to run parallel to the margin, tertiary venation scalariform, running perpendicular to the midrib thus causing the formation of a decreasing series of intermediate lateral veins, indistinct above, distinct below. *Inflorescences* terminal, pendulous, (9–)15–33 cm long; peduncle slender; racemes 0–2(–3), 3–6(–10) cm long; pairwise scales persistent at the base of peduncle; bracts caducous, triangular, c. 2–3 mm long; cymules 0.5–1(–1.5) cm apart, 1–4-flowered. *Flowers*: pedicel 3–12 mm, articulated at 1–3 mm from the base; sepals, ovate, in flower 6–7 by 2–3 mm, green-yellowish, in fruit 8–9 by 3–4 mm, persistent and accrescent, bright red; petals obovate, 7–9 by 4–5 mm, shortly clawed at base, rounded at apex, bright yellow; stamens 10, filaments less than 1 mm long, anthers 5–6 mm long, transversely wrinkled, poricidal; ovary c. 2 mm wide; style slender, 6–7 mm long. *Fruits*: receptacle a ± flattened-globose

shape, c. 3 mm wide, red; drupelets 1–4 well developed per receptacle, reniform, black at maturity; cotyledons accumbent, similar in size.

Distribution: Continental Equatorial Guinea (Rio Muni), Gabon and south-western Republic of the Congo (Niari).

Ecology: In primary and secondary forest, on creek banks and adjacent to swampy areas; at 210–1000 m altitude.

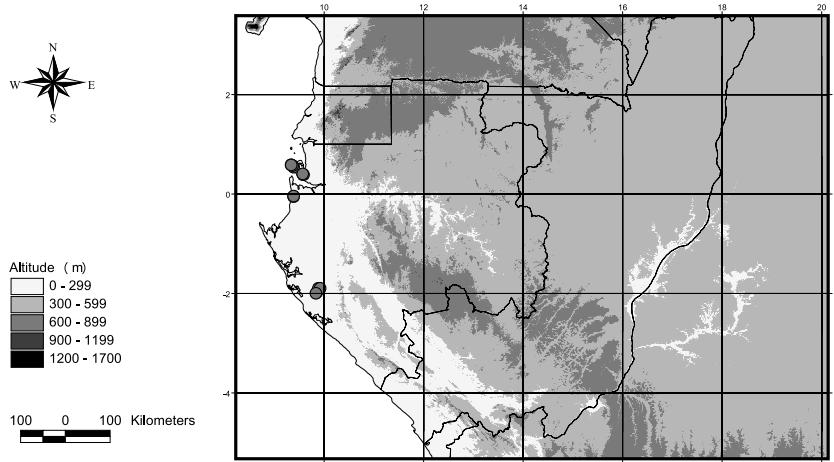

Phenology: Flowers collected in January, April, July and August; fruits collected from March to May and in August.

Preliminary IUCN conservation status: LC. EOO = 72,683 km², AOO = 23,157 km², locations = 9 (cell width = 50.79 km). This species, although being sub-endemic to Gabon, has a fairly wide distribution and hence its EOO and AOO are comparatively large, and above the IUCN thresholds. Potential future threats could come from habitat destruction (logging or land transformation) but a fair number of populations are located within protected areas (PN de Monte Alen, Monts de Cristal NP, Waka NP, Lopé Reserve). Therefore, the category of 'Least Concern' is here proposed.

Figure 5. *J.J. de Wilde* 10165 at WAG, holotype of *C. glaucifolium* Biss.

***Campylospermum occidentalis* Biss., sp. nov. — Fig. 6; Map 4****Map 4.** Distribution of *C. occidentalis* Biss.

Diagnosis: A species similar to *C. paucinervatum* Sosef, but leaf blade papery, with an acuminate apex, entire to serrulate margin and 7–11 main lateral veins on either side of the midrib; inflorescence lax, 4–8(–12) cm long, with 1–4(–6) racemes of 1–7(–11) cm long; pedicels 10–15 mm, articulating at 2–5 mm from the base.

Type: Haegens & v.d. Burgt 106 (holo WAG; iso LBV), Gabon, Ogooué-Maritime, Rabi-Kounга, road to Divangui, S1°54', E9°55', 6 Dec. 1993.

Treelet up to 4 m tall. *Stipules* caducous, 2–3 mm long. *Leaves*: petiole 2–5 mm long; leaf blade narrowly elliptic to narrowly elliptic-obovate, 6–15 by 1.5–4.5 cm, base cuneate, apex acuminate, papery, margin entire to serrulate, glossy dark green above, paler green below; midrib slightly prominent above, prominent below, main lateral veins 9–10 mm apart, 7–11 on either side, curved upward to run parallel to the margin, tertiary venation distinct on both sides, scalariform, running perpendicular to the midrib thus causing the formation of a series of slightly prominent intermediate lateral veins. *Inflorescences* terminal, lax, 4–8(–12) cm long; peduncle slender; racemes 1–4(–6), 1–7(–11) cm long, held ± horizontally, not seldom with secondary branches; pairwise scales at the base of peduncle absent; bracts early caducous; cymules (5–)10–15 mm apart, 1–2(–3)-flowered. *Flowers*: pedicel 4–10(–15) mm, articulated at 1–6 mm from the base; sepals ovate, in flower 5–7 by 2–3 mm, greenish yellow, in fruit 6–7 by 3–3.5 mm, persistent and accrescent, red; petals obovate, 5–11 by 4–7 mm, cuneate at base, rounded to emarginate at apex; stamens 10, yellow-orange, filaments less than 1 mm long, anthers 3–4 mm long; ovary c. 2 mm wide; style slender, curved, c. 4 mm long. *Fruits*: receptacle a ± flattened-globose shape, c. 3 mm wide, red; drupelets 1–3 well developed per receptacle, ellipsoid, c. 8 by 5 mm, orange to orange-red at maturity; cotyledons incumbent, similar in size.

Distribution: Endemic to Gabon, only found in the coastal plain, in the Ogooué-Maritime (Rabi-Kounga) and Estuaire (Mondah forest and Bikélé) provinces.

Ecology: Primary and secondary, moist forest, near swampy areas; on sandy soil; at 5–30 m altitude.

Phenology: Flowers collected from August to November, coinciding with the end of the long dry season and start of the main rainy season; mature fruits from November to December.

IUCN conservation status: VU. B1ab(ii, iii, iv). EOO = 5959 km², AOO = 3388 km², locations = 4 (cell width = 29.10 km). This species seems to have a disjunct distribution, but this is uncertain because the area between the two occupied areas is not well explored. In a situation involving a disjunct distribution the sliding scale grid size method leads to an overly large estimation of especially the AOO. Some of the occurrences in the vicinity of the capital Libreville are under threat of habitat destruction due to urbanization and overexploitation. This is likely to lead to a decline in the area of occupancy and/or number of populations or even extent of suitable habitat and hence we propose the category 'Vulnerable'.

Additional material: GABON, Estuaire: A.M. 2.4 New combinations

***Campylospermum andongensis* (Hiern) Biss., comb. nov.**

Ouratea reticulatum (P.Beauv.) Engl. ex Gilg var. *andongensis* Hiern, Cat. Afr. Pl. 1 (1896) 122.—*Monelasmum andongensis* (Hiern) Tiegh. (1902) 328.—*Ouratea andongensis* (Hiern) Exell (1927) 58.—Type: *Welwitsch 4604* (holo LISU; iso BM), Angola, Pungo Andongo, 1857.

***Campylospermum costatum* (Tiegh.) Biss., comb. nov.**

Monelasmum costatum Tiegh., Ann. Sci. Nat., Bot., ser. 8, 16 (1902) 333.—*Campylospermum vogelii* (Hook.f.) var. *costatum* (Tiegh.) Farron (1965) 403.—Type: *Zenker 1762* (holo P; iso B, COI, G, K, L, LY, P, S, WAG), Cameroon, Bipinde, 1898.

***Campylospermum glomeratum* (Tiegh.) Biss., comb. nov.**

Monelasmum glomeratum Tiegh., Ann. Sci. Nat., Bot., ser. 8, 16 (1902) 330.—Type: *Thollon 140* (holo P; iso A, FHO, K), Gabon, Haut Ogooué, Feb. 1895.

Note: The name *Ouratea dusenii* Engl. & Gilg, published in 1903, has been used most often in literature as the correct name for this species. Recently, Bissiengou & Sosef (2008) transferred that name to the genus *Campylospermum*. However, it now turns out that the name *Monelasmum glomeratum* Tiegh. (with type specimen *Thollon 140*) refers to the same taxon and is thus also available. Since it was published in 1902, hence one year before *O. dusenii*, *Monelasmum glomeratum* Tiegh. has priority which necessitates the new combination *C. glomeratum* (Tiegh.) Biss.

***Campylospermum longestipulatum* (De Wild.) Biss., comb. nov.**

Ouratea longestipulata De Wild., Pl. Bequaert. 4 (1929) 492.—Type: *Zenker 3577* (holo BR; iso E, G, S, US), Cameroon, Bipinde, 1908.

⁴ Botanic Garden Meise, Nieuwelaan 38, 1860 Meise, Belgium.

3.1 Introduction

The genus *Campylospermum* Tiegh. comprises some 55 species occurring in the African and Asian tropics. Continental Africa harbours 48 species distributed from Senegal to Ethiopia in the North and from Angola to northern Zambia in the South. Madagascar is occupied by some five species (Perrier de la Bâthie 1941, 1951) plus some undescribed ones. Two species are found in South and South East Asia, one from India to Sri Lanka and one from Hainan and the Philippines to Indonesia. The highest species diversity is found in the Lower Guinean floristic region, Nigeria to western Democratic Republic of the Congo (White 1979, 1983) where more than half of the species occur. This situation corroborates the high botanical species-richness of that region (Linder 2001; Mutke et al. 2001; Küper et al. 2004; Sosef et al. 2006; Estrella de la et al. 2012; Linder et al. 2012) which, contrastingly, remains one of the world's most poorly studied regions (Campbell and Hammond 1989).

3.2 Delimitation and position of *Campylospermum* within the family Ochnaceae

Campylospermum belongs to the family Ochnaceae. Many authors who treated the family recognised different subdivisions. Candolle (1811) had a narrow family concept and recognized only three genera: *Ochna* L., *Gomphia* Schreb. and *Walkera* Schreb. Candolle (1824) added the genera *Elvasia* DC. and *Castela* Turpin, previously placed with doubts in Ochnaceae and Simaroubaceae respectively (Turpin 1806; Candolle 1811). His distinction between the genera was mainly based on the characteristics of the flowers and fruits. Species that now belong to *Campylospermum* have initially been placed in *Gomphia*. That genus used to accommodate all Ochnaceae–Ourateae species with ten stamens per flower and close to *Ochna* (hence with carpels becoming free in fruit). But, Baillon (1867) found out that the older name *Ouratea* Aubl. was applicable and subsequently all species of *Gomphia* were transferred to *Ouratea* (e.g. Engler 1876). Later, some Old World genera were segregated from *Ouratea*, among which *Campylospermum* Tiegh. (Bittrich and Amaral 1994).

Planchon (1846) subdivided the family into three tribes: Gomphieae, Euthemideae and Luxemburgieae. Within the genus *Gomphia* he recognised two sections: *Eugomphia* in the New World and *Gomphiastrum* in the Old World. Those sections were based on the morphology of the stipules being either intra-axillary and fused (*Gomphiastrum*) or extra-axillary and free (*Eugomphia*).

Engler (1876) also recognised those sections and extensively studied the New World species of *Ouratea* which he, like Planchon, included in the section *Eugomphia*. Gilg (1893a) in his treatment of the family, continued using the name *Ouratea* instead of

Gomphia following Engler (1876). He also recognized two sections, though he called these *Neoouratea* (New World) and *Palaeouratea* (Old World), which he later on (Gilg 1925) raised to subgeneric level.

The next milestone in the delimitation and subdivision of the Ochnaceae was the work of Van Tieghem (1902b, 1902c, 1902a, 1903). He mostly focussed on anatomical and additional morphological characters that had not been taken into consideration by previous authors. His subdivision of the family was based on leaf anatomical characters, the position and the arrangement of the floral elements, fruit characters and seed morphology (mainly shape and position of the embryo and cotyledons). He divided the Ochnaceae into two subfamilies: Ochnoideae and Elvasioideae. He then subdivided the subfamily Ochnoideae into two tribes: Ourateeae and Ochneae. The tribe Ourateeae was, in turn, divided into two subtribes which he called Orthosperminae (America) and Campylosperminae (Africa, Madagascar and Asia). Those subtribes are identical with Gilg's (1925) subgenera *Neoouratea* and *Palaeouratea* within the genus *Ouratea*. Although Van Tieghem's contribution to the understanding of the family was of great value, he introduced an exceptionally narrow concept of genera and species. He recognized four genera in his first work (Van Tieghem 1902b), two months later twenty five, and finally ended up having thirty four genera in his 1907 work (Van Tieghem 1907). The present-day *Campylospermum* species were scattered across seven genera, and those of the genus *Ochna* for example across 15 (Callmander and Phillipson 2012). His views were followed by only few authors. Gilg (1925), although being critical about Van Tieghem's species and genus concept, largely agreed with the major subdivisions at higher levels.

Kanis (1968), accepted Engler's main division (1874) into Exalbuminosae and Albuminosae as two distinct subfamilies named Ochnoideae and Sauvagesioideae respectively. Within the Ochnoideae Kanis recognized the tribes Ochneae and Elvasieae and divided the tribe Ochneae into the subtribes Ochninae and Ourateinae. The latter two had previously been recognized by Van Tieghem at the level of tribes.

Finally, Amaral (1991) and Amaral and Bittrich (2014) agreed with the concept to include the family Luxemburgiaceae into the Ochnaceae and as a logical consequence distinguished three subfamilies: the Luxemburgioideae, the Sauvagesioideae and the Ochnoideae. They followed Kanis in the subdivision of the latter subfamily into two tribes, Ochneae and Elvasieae, and the recognition of the subtribes Ochninae and Ourateinae. At present, the latter subtribe comprises four genera (see below).

3.3 Taxonomic history of the genus *Campylospermum*

The first species of *Campylospermum* that were discovered were described as members of the genus *Gomphia* (Candolle 1811, 1824; Planchon 1846; Oliver 1868). The number of species steadily rose: Candolle (1811) mentioned three species, Planchon (1846) seven, Oliver (1868), Engler (1874) nine and Gilg (1893a) eleven. Subsequently, these were transferred to the genus *Ouratea* subgenus *Palaeouratea* section *Gomphiastrum* (Engler 1874; Gilg 1893a). It was notably Farron (1963, 1965; 1967; 1968, 1985) who, after the extensive splitting of Van Tieghem (see above), restructured the genus *Ouratea* and created the present situation with four distinct genera in the subtribe Ourateinae: *Ouratea* Aubl. (\pm 200 species), *Idertia* Farron (1 species), *Rhabdophyllum* Tiegh. (8 species) and *Campylospermum* Tiegh. (\pm 55 species) (Farron 1963; Kanis 1968; Farron 1985; Sastre 1988; Sastre 2003; Sosef 2008, 2013). This subtribe is characterized by having 10 stamens on very short filaments, carpels becoming free in fruit and a receptacle that becomes reddish and swollen in fruit. The genus *Ouratea* is restricted to the New World tropics, the genus *Campylospermum*, *Idertia*, and *Rhabdophyllum* are found in Old World tropics, with the latter two confined to continental Africa. *Ouratea* is distinct from the rest by having caducous sepals (not persistent and accrescent ones as in the other three genera) and free, extra-axillary stipules (fused and intra-axillary in the others). *Idertia* shares having a straight embryo and cotyledons with *Ouratea*, reason why Farron (1968) considered *Idertia* to represent the most primitive African genus of which *Rhabdophyllum* and *Campylospermum* are derived. *Rhabdophyllum* is sufficiently distinct from *Campylospermum* mostly because of its dense, straight and parallel secondary veins and the sepals which carry one or two dorsal flaps that interlock with the margin of the adjacent sepal in bud (Sosef 2008, 2013).

There has been some confusion as to the correct generic name for the African and Asian species of *Campylospermum*, when they are seen as generically distinct from their New World relatives. While some authors used the name *Ouratea* Aubl. for all Old and New World species (Gilg 1893a; De Wildeman 1920; Gilg 1925; Hutchinson et al. 1954; Robson 1963), others placed the Old World species in either a distinct genus using the name *Gomphia* Schreb. (Kanis 1967, 1968; Kanis 1972; Kanis 1973; Kanis 1987; Nicolson et al. 1988; Verdcourt 2005) or *Campylospermum* (Farron 1968, 1985; Sosef et al. 2007; Bissiengou and Sosef 2008; Bissiengou et al. 2013). These nomenclatural issues were based on an erroneous lectotypification by Kanis. The issue was solved by Bittrich & Amaral (1994) rendering the name *Gomphia* a full synonym of *Ouratea* which has its type species in the New World.

Campylospermum has about 55 species occurring in continental Africa, Madagascar, extending east to China and the Malesian region (Bissiengou et al. 2013). Despite of the many individual contributions, the African species of *Campylospermum* have not

been fully revised after Gilg (1925), although notably Farron (1963, 1965, 1968, 1985), Bamps & Farron (1967), Robson (1963), Verdcourt (2005) and others published useful parts for such a revisionary work of the continental species.

Farron (1968) kept some of van Tieghem's genera as sections within *Campylospermum*. He based his arrangement of six sections mainly on the shape and position of embryo and cotyledons: cotyledons being either of similar size and incumbent (section *Notocampylum*, *Diphyllodium*) or accumbent (section *Campylospermum* and *Cercanthesium*), or being dissimilar in size and incumbent (section *Monelasmum*) or accumbent (section *Campylospermum*). The more derived species of the genus *Rhabdophyllum* tend to have heterocotyledonous embryos while the primitive ones have isocotyledonous ones (Farron 1985). Species of *Idertia* have cotyledons that are similar in size, straight and accumbent. Finally, Farron's sixth section, *Bisetaria*, is based upon the distinct close leaf venation and linear, free stipules of the species *C. lecomtei* (Tiegh.) Farron. The flowers being fairly uniform throughout the genus, species distinction is generally based on characteristics of the leaf shape and venation as well as the inflorescence structure. Because of the plasticity of these character sets, the individual species are sometimes difficult to tell apart by a non-specialist.

To evaluate Farron's sectional arrangement, the cotyledon type was studied for each species. The results proved not to be consistent with Farron's observations because different types of cotyledons were present within a section. For example, within the section *Diphyllodium*, according to Farron characterized by accumbent cotyledons of similar size, those of *C. subcordatum* proved to be dissimilar in size with a small outer cotyledon. Furthermore, the species pairs *C. auriculatum* and *C. schoenleinianum* as well as *C. klainei* and *C. mannii* are morphologically highly similar but differ in cotyledon type, and would hence have to be grouped in different sections. Finally, the results of molecular work undertaken at the moment (Chapter 5) shows a phylogenetic tree with low resolution at species level. However, in the cases where species of *Campylospermum* are grouped, they do not follow Farron's sectional arrangement, except for the species of section *Cercanthesium*, which are grouped (0.99 posterior probabilities) along with species occurring in Madagascar. The above suggests that cotyledon type is a fairly unstable character, less suitable to be used for sectional delimitation. Because of this, we conclude that Farron's sections do not provide a natural grouping, and we decided not to retain any sectional arrangement in the current study.

3.4 Uses

Plants of *Campylospermum* are often very attractive in the field, especially during flowering and fruiting periods, which is why some of them are planted as ornamentals (Burkill 1997). Being shrubs or small trees, only few are useful as timber (Burkill 1997),

but a fair number have medicinal properties (Neuwinger 2000). In Liberia, the saplings of *C. squamosum* are used to bind the drum-head onto hollow log drums while the bark or pounded leaves are used in poultices to relieve body pain (Burkill 1997; Oyen 2012).

3.5 Seed dispersal

The mericarps are green or red when immature and red to black and shiny in mature state. The black ones are often contrasting with the red sepals and receptacle and as such represent a typical syndrome suggesting dispersal is by birds (Van der Pijl 1982), although no reports of direct observations are known to us.

3.6 Conservation

p.44

Our knowledge of the conservation status of many *Campylospermum* species is still limited. Some of them are known from only very few scattered collections, whereas others are known from only a very restricted area. Therefore, it was decided to add a preliminary assessment of the IUCN conservation status of each species based on the locality data of the herbarium specimens studied.

3.7 Materials and Methods

3.7.1 Taxonomy

This revision is based on herbarium material either received on loan from or studied during visits to the following herbaria: A, AAU, B, BAS, BATA, BENIN, BR, BRLU, BM, BUC, C, CNSF, COI, CSRS, E, EA, EPU, FBC, FHO, FI, FR, G, GENT, GC, GH, HBG, IAGB, IEC, IFAN, IG, K, KIS, KRIBI, L, LAMTO, LD, LBV, LIB, LISU, LISC, LMA, LUA, LY, M, MA, MAKOK, MHU, MO, NY, NHGC, NHT, OXF, P, POZG, PR, PRE, PRF, S, SCA, SL, SEGC, SERG, SRGH, STOME, TAN, UC, UCJ, UPS, US, WAG, YA, Z. Acronyms follow Thiers (2012). In addition, field observations were made during expeditions in Gabon and Cameroon (2009–2010). In total, about 5000 herbarium specimens were studied for this revision.

Furthermore, targeted searches to locate type specimens were performed using websites such as the Aluka African Plant Initiative Database (<http://www.aluka.org/page/content/plants.jsp>), the JSTOR Plant Science (<http://plants.jstor.org/>) and the GBIF portal (<http://www.gbif.org/>).

All specimen data were entered into the BRAHMS (Botanical Research and Herbarium Management System) database of the National Herbarium of the Netherlands (now part of the Naturalis Biodiversity Center). From this database specimen citation lists were generated for each taxon.

To analyse patterns of morphological variation, standard herbarium techniques were applied (Vogel 1987). Taxa were treated as being distinct at species level when they consequently differed in two or more characters. Floral dimensions were measured either from herbarium material soaked/boiled in tap water or directly from fresh samples in the field. In the descriptions, diagnostic features are given in bold. Finally, the terminology used in the species description is based on (Stearn 1992) and (Harris and Harris 2001).

3.7.2 Distribution maps and IUCN conservation status

Locality data of all specimens was geo-referenced. To produce distribution maps for each species, BRAHMS was used in combination with ArcView 3.3 software (ESRI 2002). Only specimens with accuracy of 15 arcmin or less were used to produce the maps.

To perform a preliminary assessment of the IUCN category of threat for each species, the BRAHMS software in combination with ArcView 3.3 (ESRI 2002) and the IUCN Red List add-in script developed by Moat (2007) were used. The latter calculates the AOO (area of occupancy), EOO (extent of occurrence) and number of localities for each species. The threat category of each individual species was assessed by evaluating the EOO or AOO under Criterion B (IUCN 2013) and the final preliminary assessment was performed following the IUCN guidelines (Subcommittee 2013). To estimate the AOO and EOO, an appropriate cell size was generated for each individual species. The IUCN guidelines advise to have a cell width of 2 km, but this is not deemed useful when working with herbarium records (Moat 2007). Instead we applied a sliding cell size, as advised by and implemented in the add-in of Moat (2007). Furthermore, a 'location' was defined as a single grid cell. Projected continuing decline of a species either in terms of geographic range (AOO, EOO) or of subpopulation was assessed by determining the presence of that species within protected areas and/or in areas with known present-day logging activities or other relevant threats. The location of protected areas was obtained using the World Database on Protected Areas (<https://www.protectedplanet.net>).

3.8 Genus treatment

Campylospermum Tiegh.

J. Bot. (Morot) 16: 35-40 (Febr. 1902); Bull. Mus. Hist. Nat. (Paris) 8: 215 (Apr. 1902); J. Bot. (Morot) 16: 196-197 (June 1902); Ann. Sci. Nat., sér. 8, Bot. 16: 193-296 (Dec. 1902); Farron, Bull. Soc. Bot. Suisse 73: 202 (1963); H.Perrier, Fl. Madag. 133 Ochnacees: 2-18 (1951); Farron, Bull. Jard. Bot. État Bruxelles 35: 393 (1965); Bamps & Farron, Fl. Congo Belge, Ochnaceae: 32 (1967); Farron, Candollea 23: 177-228 (1968); Farron, Bot. Helv. 95: 59-72 (1985). – Type species: *Campylospermum dybovskii* Tiegh.

Gomphia Schreb., Gen. Pl. ed. 8, 1: 291 (1789), pro parte (excl. the type); P.Beauv., Fl.

Oware 2(12): 22, t. 72 (1810); Candolle, Ann. Du Mus., XVII: 398 (1811); Planchon, London J. Bot. 24: 593 (1846); Oliver, Fl. trop. Afr. 1: 319-322 (1868); Kanis, Taxon 16: 420 (1967); Blumea 16: 51 (1968); Rev. Fl. Ceylon 6: 251 (1988); Amaral & Bittrich, Taxon 43: 89-93 (1994); Verdc., Fl. Trop. E. Africa, Ochnac.: 43-52 (2005). – Type species: *Gomphia zeylanica* (Lamk.) DC. ≡ *Gomphia serrata* (Gaertn.) Kanis.

Ouratea Aubl., Hist. Pl. Guiane: 397 (1775), nom. cons., pro parte (excl. the type); Engl. & Prantl., Nat. Pflanzenfam. ed. 1, III, 6: 79-81 (1893); Tiegh., Bull. Mus. Natl. Hist. Nat. 8: 208-218 (Jan. 1902); Gilg, Bot. Jahrb. Syst. 33: 231-275 (1904); De Wild., Rev. Zool. Afr. VII, Suppl. Bot.: B42-B71 (1920); Farron, Bull. Soc. Bot. Suisse 73: 196-217; Amaral & Bittrich, Taxon 43: 89-93 (1994). Type species: *Ouratea guianensis* Aubl.

Bisetaria Tiegh., J. Bot. (Morot) 16: 44 (Feb. 1902). – Type species: *Bisetaria lecomtei* Tiegh. ≡ *Campylospermum lecomtei* (Tiegh.) Farron.

Cercanthemum Tiegh., J. Bot. (Morot) 16: 198 (June 1902). – Type species: *Cercanthemum sacleuxii* Tiegh. ≡ *Campylospermum sacleuxii* (Tiegh.) Farron.

Notocampylum Tiegh., J. Bot. (Morot) 16: 199 (June 1902). – Type species: *Notocampylummannii* (Oliv.) Tiegh. ≡ *Campylospermummannii* (Oliv.) Tiegh.

Diphyllodium Tiegh., J. Bot. (Morot) 16: 200 (June 1902). – Type species: *Diphyllodium klainei* Tiegh. ≡ *Campylospermum klainei* (Tiegh.) Farron.

Spongopyrena Tiegh., J. Bot. (Morot) 16: 201 (June 1902). – Type species: *Spongopyrena elongata* (Oliv.) Tiegh. ≡ *Campylospermum elongata* (Oliv.) Tiegh.

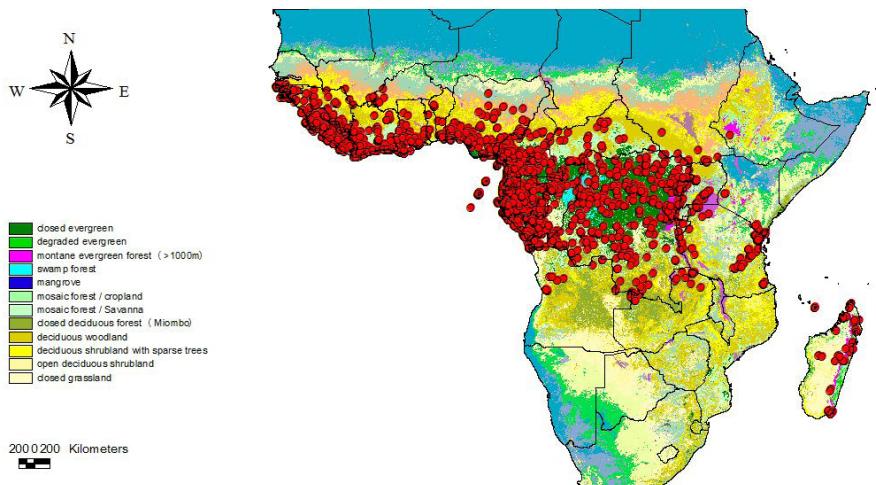

Monelasmum Tiegh., J. Bot. (Morot) 16: 202 (June 1902). – Type species: *Monelasmum reticulatum* (P.Beauv.) Tiegh. ≡ *Campylospermum reticulatum* (P.Beauv.) Farron.

Exomicrum Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 338 (Dec. 1902) & Bull. Mus. Nat. Hist. Nat. 8: 547 (Dec. 1902). – Type species: *Exomicrum glaberrimum* (P.Beauv.) Tiegh. ≡ *Campylospermum glaberrimum* (P.Beauv.) Farron.

Trees, treelets or shrubs, monocaulous or with branched stem, glabrous. ***Stipules intrapetiolar***, caducous or persistent, **fused** or rarely free (*C. lecomtei*), triangular to linear. Leaves sessile or petiolate; petiole often wrinkled; leaf blade often coriaceous, with entire to serrate margin, often decurrent onto the petiole; venation: main lateral veins well-spaced or rarely numerous and dense (*C. lecomtei*), **slightly to strongly curved up to run subparallel to the margin** or rarely straight (*C. lecomtei*), secondary lateral veins not reaching the margin, tertiary venation scalariform, sometimes reticulate towards the midrib or rarely reticulate, distinct to indistinct. ***Inflorescence terminal*** or rarely axillary, **generally composed of sessile to subsessile cymules arranged in racemes** that can be in turn solitary or branched, rarely reduced to 1-2 flowers; pairwise scales at the base of peduncle present or absent. ***Flower:*** bracts caducous or

persistent; pedicel articulated above the base, part below the articulation persistent; sepals 5, quincuncial in bud, green to yellowish in flower, **persistent, accrescent and turning red in fruit**; petals 5, contort, longer than the sepals, yellow or rarely whitish or orange, cuneate or rarely shortly unguiculate at a base; **stamens 10**, in two whorls, free, filaments stout, **much shorter than the anthers**, generally less than 1 mm long, usually persistent, anthers yellow, narrowly to very narrowly pear-shaped, transversely wrinkled, poricidal, caducous; carpels 5, **fused below but eventually free in fruit**, 1-ovulate; style 1, slender, gynobasic, bent outward, stigma terminal, small. *Fruit*: **receptacle an inflated ± flattened-globose shape, red**; 1 to 5 well developed drupelets per fruit, reniform to ellipsoid or almost globose, passing through green or red to black at maturity; **cotyledons incumbent or accumbent, curved**, equal to strongly dissimilar in size.

A genus of about 55 species, 48 of which are widely distributed in tropical Africa (see **Map 1**), about five occurring in Madagascar, and 2 species in South and South-East Asia from India to Sri Lanka, Hainan, and the Philippines to Indonesia.

Map 1. Distribution of the African *Campylospermum*

3.9 Key to the continental African species of *Campylospermum*

- Monocaulous trees, hence with unbranched stem; leaves crowded at the end of the stem (collecting litter); leaf blade 17-70(-90) cm long, narrowly spatulate to narrowly elliptic-obovate or rarely narrowly elliptic; tertiary venation perpendicular to the main laterals 2
 - Shrubs or trees with branched stem; leaves well-spaced along the twigs; leaf blade generally 4-95 cm long, (very) narrowly elliptic to (very) narrowly obovate

- or elliptic to obovate; tertiary venation usually perpendicular to the midrib 7
2. - Inflorescence branched, or sometimes with a bundle of 2-5 sessile racemes 3
 - Inflorescence unbranched 5
 3. - Inflorescence axillary, very dense and corymbose, or with a bundle of 2-5 sessile racemes; leaf base broadly cuneate to cordate 4
 - Inflorescence terminal, with 1-5 racemes on a distinct peduncle; leaf base auriculate *C. amplexens*
 4. - Inflorescence very dense, highly branched and corymbose, with many short racemes of up to 1.5 cm long *C. duparquetianum*
 - Inflorescence with a bundle of 2-5 racemes of (3-)13-28(-35) cm long, sitting on top of a long peduncle carrying two leafy bracts at the apex *C. subcordatum*
 5. - Peduncle distinctly flattened, strap-like, 23-60(-83) cm long *C. elongatum*
 - Peduncle angular to slightly flattened, 8-25(-32) cm long 6
 6. - Inflorescence terminal on a short lateral twig, 3-4 cm long; peduncle with 2 subopposite reduced leaves or leafy bracts at the base *C. klainei*
 - Inflorescence axillary, without reduced leaves or leafy bracts *C. mannii*
 7. - Leaf base auriculate to cordate; leaf blade with 16-30 main lateral veins 8
 - Leaf base attenuate to cuneate or slightly cordate, rarely cordate but then leaves with 30-50 main lateral veins 9
 8. - Leaf blade with 16-19 main lateral veins; inflorescence 12-15(-18) cm long; sepals 7-8 mm long in flower, 9-10 mm long in fruit; cotyledons dissimilar in size, with a small outer cotyledon (Equatorial Guinea and Gabon) *C. auriculatum*
 - Leaf blade with 20-30 main lateral veins; inflorescence (10-)12-27(-39) cm long; sepals 5-7mm long in flower, 6-7 mm long in fruit; cotyledons similar in size (West Africa) *C. schoenleinianum*
 9. - Leaf margin spinose-serrate, at least in the apical half 10
 - Leaf margin entire to serrulate or serrate 11
 10. - Leaf blade (3-)5-8(-9) cm wide, with 11-25 main lateral veins 5-25 mm apart; cotyledons dissimilar in size, with a small outer cotyledon; stipules 4-5 mm long (West and Central Africa) *C. flavum*
 - Leaf blade (1.5-)2-3(-4.5) cm wide, with 3-12 main lateral veins 15-30(-70) mm apart; cotyledons similar in size; stipules 2-3 mm long (Tanzania, Zambia and

south-eastern Democratic Republic of the Congo)

C. lunzuense

11. - Inflorescence axillary, unbranched; peduncle flattened (southern Kenya and Tanzania) 12
 - Inflorescence terminal, branched or unbranched; peduncle cylindrical or occasionally flattened but then inflorescence distinctly branched 13
12. - Leaf blade (4-)6-10(-13) cm wide, with an acute to acuminate apex; peduncle (7-)9-28(-39) cm long; tertiary venation scalariform, perpendicular to the main lateral veins *C. sacleuxii*
 - Leaf blade (2-)3-5(-7) cm wide, with an obtuse to rounded apex; peduncle 3-15 cm long; tertiary venation reticulate, except for a few scalariform veinlets, perpendicular to the midrib *C. scheffleri*
13. - Leaf blade linear to very narrowly elliptic (length/width ratio > 8), rarely ratio as low as 4.5 but then midrib running through a gully 14
 - Leaf blade narrowly elliptic or broader (length/width ratio < 7), when midrib prominent on upper side, ratio always lower than 7 15
14. - Leaf blade with curved, well-spaced main lateral veins; stipules narrowly triangular, c. 3 mm long; inflorescence branched *C. louisii*
 - Leaf blade with straight and closely spaced main lateral veins; stipules linear, 5-13 mm long; inflorescence unbranched *C. lecomtei*
15. - Leaf blade with 0-7 main lateral veins, up to 10(-14) x 2(-3) cm 16
 - Leaf blade with (7-)9-more main lateral veins, generally longer and broader 17
16. - Leaf blade with 4-7 main lateral veins and acute apex; racemes 3-6(-9) cm long *C. glomeratum*
 - Leaf blade with 0-2(-5) main lateral veins, the very apex apiculate; racemes 1-3 cm long *C. paucinervatum*
17. - Leaf blade obovate, (24-)28-45(-53) x (8-)11-14(-17) cm; sepals in flower 9-10 x 6-7 mm, strongly enlarged in fruit to (20-)25-30(-35) x (10-)13-20(-25) mm (southern Cameroun and northern Gabon) *C. umbricola*
 - Leaf blade generally smaller; sepals in flower up to 4 mm wide, in fruit up to 6 mm (tropical Africa) 18
18. - Leaf blade distinctly bullate 19
 - Leaf blade not or sometimes slightly bullate 25

- 3**
p.50
- 19. - Stipules 14-17 mm long; leaf blade with tertiary venation indistinct on both sides; inflorescence unbranched, 2-4 cm long, very dense, the cymules 1-2 mm apart *C. longestipulatum*
 - Stipules 2-13(-25) mm long; leaf blade with tertiary venation distinct, at least on the lower side; inflorescence branched or unbranched, (1-)3-more cm long, with cymules \geq 3 mm apart 20
 - 20. - Inflorescence unbranched, dense, cymules even at the base of the inflorescence up to 10 mm apart; sepals 7-10 x 2-4 mm in flower, 9-12 x 3-6 mm in fruit 21
 - Inflorescence branched or unbranched, lax, cymules at least at the base of the inflorescence 10-20 mm apart, rarely inflorescence fairly dense and cymules closer together but then sepals 5-7 x 1.5-2 in flower and 6-8 x 2-3 mm in fruit 22
 - 21. - Leaf blade with distinctly prominent midrib above, 10-16 main lateral veins on either side and scalariform tertiary veins running perpendicular to the midrib *C. sulcatum*
 - Leaf blade with midrib flat above, 14-27 main lateral veins on either side and scalariform tertiary veins running perpendicular to the main laterals *C. gabonense* subsp. *australe*
 - 22. - Inflorescence composed of 1-3 long racemes sitting close together terminal on the twig; flowers on a 4-5 mm long pedicel; sepals 3-4 mm long in flower, c. 5 mm long in fruit *C. descoingsii*
 - Inflorescence single, branched or occasionally unbranched, but then pedicels and sepals longer 23
 - 23. - Leaf blade with tertiary venation very distinct and prominent on both surfaces; pairwise scales at base of inflorescence absent *C. excavatum*
 - Leaf blade with tertiary venation indistinct to distinct but never prominent; pairwise scales at base of inflorescence persistent 24
 - 24. - Inflorescence with 2-7 racemes; leaf blade with tertiary venation indistinct above, fairly distinct below; pedicels articulated at 2-4 mm from the base; cotyledons accumbent, similar in size *C. calanthum*
 - Inflorescence with 0-3 racemes; leaf blade with tertiary venation distinct on both surfaces; pedicels articulated at 1-2 mm from the base; cotyledons incumbent, dissimilar in size *C. claessensii*
 - 25. - Leaf blade with rounded to cordate base; each pedicel supported by c. 3 tiny bracts *C. oliveri*
 - Leaf blade with attenuate to cuneate base, rarely rounded but then each pedicel

supported by only 1 tiny bract	26
26. - Leaf glaucous (greyish) above when dry; plants either with a pendulous inflorescence or with a combination of papyraceous leaves, a short (up to 4(-6) cm) and dense inflorescence and stipules of 3-4 mm long	27
- Leaf not glaucous above when dry; inflorescence erect to erecto-patent	28
27. - Inflorescence pendulous, lax, (9-)15-33 cm long	<i>C. glaucifolium</i>
- Inflorescence erect to erecto-patent, dense, (1-)2-4(-6) cm long	<i>C. glaucum</i>
28. - Inflorescence unbranched or rarely with 1-2 short, up to 4 cm long, racemes at the base, dense	29
- Inflorescence branched, racemes generally longer than 4 cm, lax	33
29. - Leaf blade slightly bullate (main lateral veins in a shallow depression)	30
- Leaf blade flat	32
30. - Leaf blade with tertiary venation consisting of closely spaced and fine parallel veinlets; pedicels articulating at the very base; cotyledons similar in size	<i>C. congestum</i>
- Leaf blade with tertiary venation with more widely spaced parallel veinlets; pedicels generally articulated at ≥ 2 mm from the base; cotyledons dissimilar in size	31
31. - Leaf blade (6-)9-17(-21) x (2-)3-6(-7) cm, with tertiary scalariform veinlets running perpendicular to the midrib, 10-16 main lateral veins on either side; pedicels articulating at 2-3 mm from the base	<i>C. sulcatum</i>
- Leaf blade 16-30(-35) x 6-10(-11) cm, with tertiary scalariform veinlets running perpendicular to the main laterals, 14-27 main lateral veins on either side; pedicels articulating at 3-9 mm from the base	<i>C. gabonense</i> subsp. <i>australe</i>
32. - Leaf blade (5-)7-14 x (1.5-)2-4 cm, with 10-14 main lateral veins on either side; pedicels articulating at 1-2 mm from the base	<i>C. cabrae</i>
- Leaf blade 16-30(-35) x 6-10(-11) cm, with 14-27 main lateral veins on either side; pedicels articulating at 3-9 mm from the base	<i>C. gabonense</i> subsp. <i>gabonense</i>
33. - Leaf blade with main lateral veins indistinct to at most slightly prominent above, tertiary venation indistinct above	34
- Leaf blade with main lateral veins prominent above, tertiary venation distinct above	36

- 3
p.52
34. - Leaf blade (3-)5-16 x (1.5-)2-6 cm; twigs with pale brownish bark *C. glaberrimum*
 - Leaf blade (11-)16-32(-40) x (3-)5-9(-12) cm; twigs with dark coloured bark 35
35. - Leaf blade with main lateral veins not or slightly prominent below; inflorescence with ascending racemes *C. densiflorum*
 - Leaf blade with main lateral veins prominent below; inflorescence with horizontal racemes *C. dybowskii*
36. - Petiole (5-)10-20(-25) mm long; leaf blade decurrent onto the petiole or leaf margin thickened and recurved 37
 - Petiole (0-)2-7(-10) mm long; leaf blade not decurrent onto the petiole and leaf margin not thickened and recurved 38
37. - Leaf blade not decurrent onto the petiole, margin thickened and recurved; racemes erecto-patent to horizontal, (2-)5-9(-14) cm long *C. laeve*
 - Leaf blade decurrent onto the petiole, margin not thickened nor recurved; racemes horizontal, (3-)8-23(-40) cm long *C. engama*
- 38 - Leaf margin sharply serrate 39
 - Leaf margin entire to serrulate 40
39. - Leaf blade coriaceous, with 9-12 main lateral veins on either side *C. andongense*
 - Leaf blade papyraceous, with 12-17 main lateral veins on either side *C. bukobensis*
40. - Leaf blade dark brown when dry, with blunt to rounded apex, tertiary venation distinctly reticulate throughout the leaf *C. lutambense*
 - Leaf blade greenish to reddish brown when dry, with acute to acuminate apex, tertiary venation scalariform at least in the marginal zone 41
41. - Pedicels articulated at (4-)6-10 mm from the base; racemes slender and wiry *C. nutans*
 - Pedicel articulated at 1-6 mm from the base; racemes fairly stout 42
42. - Racemes branched, giving the inflorescence a corymbose appearance; inflorescence 4-8(-12) cm long *C. occidentale*
 - Racemes unbranched; inflorescence (3-)5-more cm long 43
43. - Peduncle flattened 44
 - Peduncle cylindrical 45
44. - Inflorescence born on a very robust flattened twig; pedicels 3-7 mm long, stout, articulated at 1-2 mm from the base *C. costatum*

- Inflorescence born on a slender twig; pedicels 6-13 mm long, articulated at 3-7 mm from the base *C. vogelii*
45. - Upper leaf surface set with tiny bumps in between the tertiary veinlets (strong lens!), giving the surface a 'rough' appearance *C. laxiflorum*
 - Upper leaf surface smooth in between the tertiary veinlets 46
46. - Racemes with several bracts at the top; drupelets ellipsoid-oblong, 8-14 mm long *C. plicatum*
 - Racemes without apical bracts; drupelets reniform or subglobose to ellipsoid, 5-9 mm long 47
47. - Leaf blade tertiary venation with a pattern of very closely spaced veinlets running parallel to the scalariform veins; cotyledons similar in size *C. warneckei*
 - Leaf blade tertiary venation without such veinlets; cotyledons dissimilar in size 48
48. - Pairwise scales at the base of the peduncle and bracts below each cymule persistent; leaf blade with tertiary venation on lower surface more or less unicolourous with the leaf mass; racemes held ± horizontally *C. squamosum*
 - Pairwise scales at the base of the peduncle and bracts below each cymule caducous; leaf blade with tertiary venation on lower surface markedly darker than the leaf mass; racemes erecto-patent *C. reticulatum*

***Campylospermum amplexens* (Stapf) Farron**

Fig. 1

Bull. Jard. Bot. État Bruxelles 35: 393 (1965). – *Gomphia amplexens* Stapf, J. Linn. Soc., Bot. 37: 87 (1905). – *Ouratea amplexens* (Stapf) Engl., Pflanzenw. Afr. 3, 2: 488 (1921). – Type: A. Whyte s.n. (holotype: K!), Liberia, Montserrado, Kakata, within 20 miles of Kakatown, 1904.

Tree up to 12 m tall, monocaulous; stem with brownish coloured bark. ***Stipules caducous*,** triangular, 3-5 mm long. ***Leaf:*** petiole 0-10 mm long; leaf blade **narrowly obovate to narrowly spatulate, 17-38 × 4-9 cm**, ratio **3.2-4(-4.3)**, **base auriculate, apex acute**, coriaceous, not bullate, margin **serrulate**, upper side dull green, lower side glossy paler green; midrib slightly flattened on upper side, prominent on the lower, main lateral veins **20-30 on either side, 10-20(-30) mm apart, prominent on the upper leaf surface**, more or less at a right angle with midrib but curved upward to run parallel to the margin, intermediate lateral veins less prominent on both sides, **1 to 2** in between each pair of main laterals, tertiary venation scalariform, **perpendicular to the main lateral veins, indistinct on upper side, distinct on the lower one.** *Inflorescence*

terminal or rarely axillary, branched, dense, its main axis **3–13(–19) cm long, robust, round in cross section**; racemes **1–5, 3–6(–9) cm long**; pairwise scales **caducous**; bracts caducous, triangular, c. 2–3 mm long; cymules 5–7(–15) mm apart, **1–8(–16)-flowered**. **Flower:** pedicel 7–20 mm, articulated at 3–5 mm from the base; sepals oblong, in flower 5–6 × 3–4 mm, in fruit 10–15 × 5–6 mm and enclosing the drupelets, base truncate, apex obtuse; petals **obovate**, 9–13 × 5 mm, **shortly clawed at base, truncate and slightly emarginate at apex**; stamens: anthers 6–7 mm long; ovary c. 2 mm long; style slender, 6–8 mm long. **Fruit:** receptacle c. 3 mm thick; drupelets: 1 to 4 well developed per receptacle, **ellipsoid**, c. 7 × 5 mm; cotyledons **incumbent, similar in size**.

Notes: This species is closely related to *C. mannii* (Oliv.) Tiegh. and *C. klainei* (Tiegh.) Farron. It differs by having a branched inflorescence while the other two species have an unbranched one. It is also distinguished by its distinctly auriculate leaf base (resp. cordate to auriculate and cordate in *C. mannii* and *C. klainei*). Both *C.mannii* and *C. klainei* have angular to slightly flattened peduncle while *C. amplexens* has a rounded one. The tertiary venation is distinct on both sides in *C.mannii* and *C. klainei* whereas it is indistinct on the upper side in *C. amplexens*.

Still, knowing that habitat destruction in western Africa has been severe, a more detailed assessment is desirable.

Distribution: West Africa, from Sierra Leone to Ghana (**Map 2**).

Ecology: in high, closed, evergreen, primary or secondary rain forest, also in forest along streams; at 20–350 m altitude.

Phenology: flowers observed from September to March and mature fruits from October to March.

Uses: The wood is flexible and splinters. In Liberia, the fine wood splints are tied together to make brooms (Burkhill 1997).

IUCN conservation status: LC B1/B2ab(iv). EOO=184,468 km², AOO=165,172 km², locations=29, (cell width=109 km). This species is fairly common; its most recent collection is from 2012. The number of locations is sufficient to assign this species to the category of Least Concern.

Campylospermum andongense (Hiern) Biss.

Campylospermum andongensis (Hiern) Biss., Blumea 58: 6 (2013). – *Ouratea reticulatum* (P.Beauv.) Engl. ex Gilg var. *andongensis* Hiern, Cat. Afr. Pl. Welw. 1: 122 (1896). – *Monelasmum andongensis* (Hiern) Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 328 (1902). – *Ouratea andongensis* (Hiern) Exell, J. Bot. 65: 58 (1927). – Type: *Welwitsch 4604* (holotype: LISU!; isotype: BM!, C!, COI!, G!, K!) Angola, Pungo Andongo, 1857.

Tree up to 7 m tall, with branched trunk; twigs with dark coloured bark. **Stipules caducous**, triangular, 3–5 mm long. **Leaf**: petiole 2–5 mm long; leaf blade ovate-oblong or narrowly elliptic to narrowly elliptic-ovate, **(5-)10-21 × (1.5-)3-6 cm**, ratio **(1.8-)2.6-3.75(-4.35)**, base cuneate, apex acute to slightly acuminate, chartaceous to coriaceous, not bullate, margin **serrate**, **teeth with a dark tip**, upper side dark green, lower side light green; venation: midrib prominent on both sides, main lateral veins **9-12 on either side**, **5-20 mm apart**, more or less at right angle with midrib but curved upward to run parallel to the margin, prominent above, not prominent but distinct below, intermediate lateral veins 0–1 in between each pair of main laterals, less prominent on both sides, tertiary venation scalariform, perpendicular to the midrib, **distinct on both sides**. **Inflorescence** terminal, branched, lax, its main axis **3-15(-20) cm long**; racemes **(0-)1-3(-5), (1-)3-10(-13) cm long**; pairwise scales **at the base of peduncle caducous**; bracts caducous; cymules 5–15 mm apart, 1–8-flowered. **Flower**: pedicel 7–15 mm, articulated at 1–4 mm from the base; sepals ovate to narrowly elliptic-ovate, in flower 7–8 × 2–3 mm, in fruit 8–9 × 2–3.5 mm, not enveloping the drupelets, base truncate, apex obtuse; petals **obovate**, 8–10 × 5–8 mm,

cuneate at base, rounded at apex; stamens: filaments less than 1 mm long, anthers 5–6 mm long; ovary c. 2 mm large; style slender, 5–6 mm long. *Fruit:* receptacle c. 5 mm thick; drupelets: 1 to 2 well developed per receptacle, **ellipsoid to almost globose**, (6–)8–9 × (4–)5–6 mm; cotyledons **incumbent, dissimilar in size with a small outer cotyledon.**

Notes: This species is similar to *C. reticulatum* (P.Beauv.) Farron. However, it has a more coarsely serrate leaf margin with teeth having a dark tip and petals rounded at the apex, whereas *C. reticulatum* has a serrulate margin with unicolourous teeth and petals with an emarginate apex.

Distribution: Democratic Republic of the Congo (Katanga), northern Angola, north-western Zambia (**Map 2**).

Ecology: in evergreen, riparian forests; at 700–1500 m altitude.

Phenology: flowers observed from September to January and fruits in October, December and February.

IUCN conservation status: LC B1/B2ab(i,ii,iii). EOO=268,354 km², AOO=78,240 km², locations=22, subpopulations=3, (cell width=114 km). This species is distributed across 3 subpopulations with the main one occurring in the Lavushi Manda National Park in Zambia. It is fairly well represented in herbaria, and therefore the category of Least Concern seems most appropriate.

Key literature: Exell & Mendonça (1951), Farron (1965) and Robson (1963).

***Campylospermum auriculatum* Biss.**

Blumea 58: 2 (2013). – Type: *Strijk* 73 (holotype: WAG!; isotype: LBV!), Gabon, Woleu-Ntem, Bordamur concession area, some 40 km from WWF-station, 1°14'N, 11°53'E, October 10th, 2002.

Treelet up to 6 m tall, with branched trunk; twigs with pale brown coloured bark. *Stipules* caducous, 3–5 mm long. *Leaf*: petiole 0–2 mm long; leaf blade elliptic-obovate to oblanceolate, **(9–)14–24(–31) x (4–)6–8(–11) cm, ratio 2–4(–5)**, base **auriculate to deeply cordate, often clasping the twig**, apex acute, coriaceous to thick leathery, not bullate, margin serrate, upper surface glossy green, lower surface dull paler green; midrib flattened above, prominent below, main lateral veins 16–19 on either side, 10–20 mm apart, curved upward to run parallel to the margin, intermediate lateral veins prominent on both sides, 0 to 2 in between each pair of main laterals, tertiary venation scalariform, **very distinct on both sides**. *Inflorescence* terminal or rarely axillary, branched, fairly dense, its main axis 12–15(–18) cm long, **flattened**; racemes 1–6, 3–9(–11) cm long; pairwise scales absent; bracts persistent at the base of the raceme and pedicel, triangular, c. 3–5 mm long; cymules 5–9 mm apart, 2–4(–6)-flowered. *Flower*: pedicel 5–7 mm long, articulated at 2–3 mm from the base; sepals 5, ovate, in flower 7–8 x 2–3 mm, yellowish green, in fruit 9–10 x 3–4 mm, bright red; petals 5, obovate, 7–12 x 3–4 mm, cuneate at base, rounded at apex, bright yellow; stamens: anthers 3–4 mm long; ovary c. 2 mm wide; style c. 4 mm long. *Fruit*: receptacle c. 5 mm wide, orange-red; drupelets 1 to 3 well developed per receptacle, reniform, c. 8 x 5 mm; cotyledons incumbent, dissimilar in size with a small outer cotyledon.

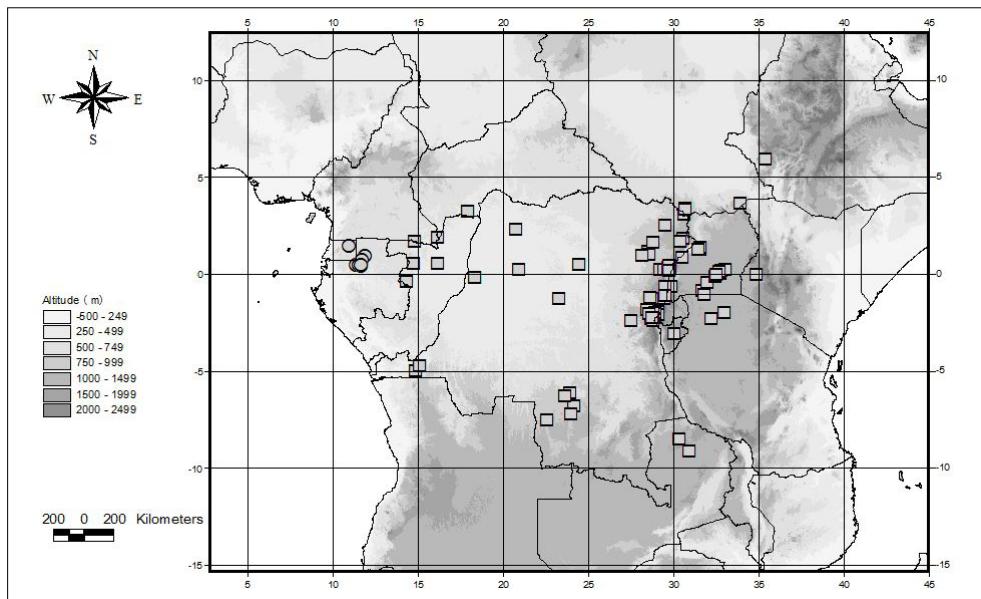

Note: Especially the auriculate to deeply cordate leaf base is highly reminiscent of *C. schoenleinianum* (Klotzsch) Farron, a species confined to western tropical Africa (from Guinea to Ghana).

Distribution: Equatorial Guinea (Rio Muni) and Gabon (Woleu-Ntem province) (**Map 3**).

Ecology: in primary or secondary forest; on brown clay soil; at 475–600 m altitude.

Phenology: flowers and mature fruits collected from October to November, flowers also observed in April, which coincides with the two rainy seasons.

IUCN conservation status: VU B1/B2ab(ii,iii,iv). EOO=6,098 km², AOO=1,653 km², locations=11 (cell width=15.36 km). All collections are of comparatively recent origin (the oldest one is from 1983). The only collection from Equatorial Guinea is from within a protected area (Inselberg at Akuom). The other ten collections from Gabon are from a fairly restricted area where logging companies operate which is supposed to lead to a decline in the AOO and/or extent of suitable habitat and hence the ‘Vulnerable’ category has been assigned.

Map 3. Distribution of *Campylospermum auriculatum* (○) and *Campylospermum bukobense* (□)

Specimens examined:

***Campylospermum bukobense* (Gilg) Farron**

Bull. Jard. Bot. État 35: 393 (1965). – *Monelasmum bukobense* (Gilg) Tiegh., Ann. Sci. Nat., ser. 8, Bot. 18: 36 (June 1903). – *Ouratea bukobensis* Gilg, Bot. Jahrb. Syst. 33: 271 (1904). – Syntypes: Stuhlmann 978, 1023, 1073, 1467, 1521, 3212, 3721, 3990, 3991, 4063 (B, none located and probably all destroyed) Tanzania, Bukoba. – Neotype (designated here): Conrads 447 (holotype: B!; isotype: BR!, EA!, FHO!, K!) Tanzania, Marienhof Ukerewe, November 21st, 1911.

Ouratea floribunda De Wild., Rev. Zool. Afr. VII, Suppl. Bot.: B51 (1920). – *Gomphia floribunda* (De Wild.) Lye, Lidia 4(3): 92 (1998) (non *Gomphia floribunda* A.St.-Hil., 1825).

– Type: Pynaert 522 (holotype: BR(3x)!; isotype: K!, Z!), Congo, Eala, October 5th, 1906.

Ouratea likimiensis De Wild., Rev. Zool. Afr. VII, Suppl. Bot.: B59 (1920). – *Gomphia likimiensis* (De Wild.) Verdc., Fl. trop. E. Afr., Ochnaceae: 46 (2005). – Type: Malchair 271 (holotype: BR!; isotype: BR!), environ de Likimi, June 10th, 1910.

Tree up to 10 m tall, bole up to 30 cm dbh, with branched trunk; twigs with pale coloured bark. *Stipules* caducous, triangular, 1–3 mm long. *Leaf*: petiole 1–5 mm long; leaf blade narrowly elliptic to oblanceolate, **(6-)8-18(-21) x (1-)1.5-5.5 cm, ratio 3-5**, base cuneate, apex acute, **papyraceous**, not bullate, upper surface glossy, lower surface dull green, margin **regularly serrate to serrulate**, the teeth with a dark tip; midrib prominent above and below, main lateral veins **12-17** on either side, 5–15 mm apart, prominent above and below, at a ± right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins 1–2(–5) in between each pair of main laterals, prominent on both sides, tertiary venation **scalariform, perpendicular to the midrib, joined by cross veinlets**, very distinct on both sides. *Inflorescence* terminal, fairly lax to fairly dense, its main axis (2-)4–16(–20) cm long; racemes 2–7, (1-)3–12 cm long, ascendant, cymules 2–15 mm apart, 2–7(–11)-flowered. *Flower*: pedicel 8–17(–20) mm, articulated at 1–6 mm from the base; sepals ovate, in flower 6–7 x 2–3 mm, in fruit 8–9 x 2–3 mm, becoming coriaceous, first spreading then curved up; petals obovate, 5–9 x 4–6 mm, base cuneate, apex rounded; stamens: anthers 3–5 mm long; ovary 1 x 1 mm; style 4–6 mm long. *Fruit*: receptacle c. 1 mm long in flower, 5 x 5 mm in fruit; drupelets 2–4 well developed per receptacle, ellipsoid, 7–10 x 5–7 mm; **embryo incumbent, dissimilar in size with a small outer cotyledon**.

Notes: The syntype specimens of *O. bukobensis*, all Stuhlmann collections, are missing. Many requests were sent out to herbaria in order to locate duplicates of those specimens. Unfortunately these could not be traced. A Neotype, *Conrads* 447, is therefore designated here. It is has been collected approximately at the same locality as the syntype specimens. The year of collection was 1911, before the Berlin herbarium, where Stuhlmann's collections were most likely kept, was largely destroyed. It has been distributed to five herbaria and two herbarium sheets are from the herbarium of Berlin (B). They carry labels with "Ouratea bukobense Gilg" in Gilg's handwriting. In addition, the serrate leaf margin and the leaf blade shape match perfectly the original description. Verdcourt (2005) recognizes *G. likimiensis* and has identified *C. bukobense* material as either *G. vogelii* or *G. likimiensis*. Actually, *G. likimiensis* is *Ouratea floribunda* De Wild but he could not use that name since *Gomphia floribunda* A.St.-Hil. exists already. He listed characters that describe both species such as the leaf texture, shape and margin. Material that has thin, narrowly elliptic-lanceolate leaves with usually spinulose teeth that are more closely spaced and more curved was identified as *O. likimiensis*. I

totally agree with him that two taxa are involved, but Verdcourt failed to see that his *C. likimiensis* also perfectly matches the description of *C. bukobense*. Verdcourt's error was maybe a logical one because he did not see any type specimens of *C. bukobense*. Now, having selected a neotype specimen and having seen many herbarium sheets identified by previous botanists as either *C. bukobense* or *O. floribunda*, to me it is obvious they belong to the same taxon, for which the correct name is *C. bukobense*.

Finally, in terms of affinity, *C. bukobense* is close to *C. andongensis*. It differs by having papyraceous leaves and more numerous lateral veins.

Distribution: South Central African Republic to South-East Cameroon and the North of the Republic of the Congo, extending to the Democratic Republic of the Congo, southern Ethiopia, southern Soudan, Uganda, Kenya, Tanzania and Zambia (**Map 3**).

Ecology: in primary, secondary and gallery forests, also in swamp forest; at 350-1650 m altitude.

Phenology: flowering and fruiting all year round.

IUCN conservation status: LC B1/B2ab(i,ii). EOO=31,36920 km², AOO= 19,82420 km², locations=82, subpopulations=26, (cell width=266 km). This species is scattered into many subpopulations (26) from the Republic of the Congo to eastern and north-eastern Africa. Although its most recent collection is from the nineteen eighties, it is well represented in herbaria suggesting it is not uncommon. Therefore, the category of Least Concern seems most appropriate.

***Campylospermum cabrae* (Gilg) Farron**

Fig. 2

Bull. Jard. Bot. État Bruxelles 35: 393 (1965). – *Exomicrum cabrae* (Gilg) Tiegh., Ann. Sci. Nat., Bot. sér. 8, 18: 38 (June 1903). – *Ouratea cabrae* Gilg, Bot. Jahrb. Syst. 33: 262 (1904). – Type: *Cabra* 33 (holotype: BR!) Congo.

Treelet up to 5 m tall, with branched stem; twigs with a pale brownish coloured bark. **Stipules persistent, very narrowly triangular, 12–15 mm long.** Leaf: petiole 2–6 mm long, slender; leaf blade narrowly elliptic, **(5–)7–14 x (1.5–)2–4 cm**, ratio 3–6, base attenuate, sometimes decurrent onto the petiole, apex slightly acuminate to acute, papyraceous, not bullate, upper surface medium green, lower surface paler green, dull on both sides, margin **regularly serrulate, teeth with a dark tip;** venation: midrib **prominent above, flat to slightly canaliculate below,** main lateral veins 10–14 on either side, 5–10(–15) mm apart, slightly prominent above, flat below, more or less at a right angle with the midrib but curved upward to run parallel to the margin, intermediate lateral veins 0–1 between each pair of main laterals, distinct on both sides, tertiary venation scalariform, running perpendicular to the midrib, distinct on both sides. **Inflorescence** terminal, **unbranched** or rarely with a short sidebranch at its base, dense; pairwise scales persistent at the base of the peduncle; peduncle axis 2–5 cm long; cymules 5–7 mm apart, 1–5-flowered; bracts **persistent**, triangular-ovate to broadly ovate, 2–3 mm long, excluding the sometimes caudate apex. **Flower:** **pedicel 5–10 mm long, articulated at 1–2 mm from the base;** sepals ovate, in flower 5–6 x 2–3 mm, base truncate, apex acute, in fruit 5–8 x 3 mm and becoming coriaceous, curved up in fruit; petals **obovate to elliptic**, 6–8 x 2–3 mm, clawed at base, **rounded to slightly emarginate at apex;** stamens: anthers 5–6 mm long; ovary 1–2 mm long; style 4–5 mm long. **Fruit:** receptacle c. 1 mm thick in flower, in fruit 2–3 mm, red; drupelets 1 to 2 well developed per receptacle, **ellipsoid**, 6–7 x 4–5 mm, immature ones reddish, mature ones black; **cotyledons incumbent, dissimilar in size with a small outer cotyledon.**

Notes: *C. cabrae* is a rare species. The above description is based on only 8 specimens, collected between 1897 and 1966. It is characterized by having a serrulate margin with black tipped teeth and narrowly triangular stipules. It seems close to *C. glaucum* with which it shares the same type of tertiary venation and short unbranched inflorescence, but which differs in having much shorter stipules and the cymules being 2–5 mm apart.

Distribution: southern Republic of the Congo, south-western Democratic Republic of the Congo (Mayombe) and Angola (Cabinda) (**Map 4**).

Ecology: in primary and secondary forest; at altitudes below 500 m.

Phenology: flowering in October, March and June; fruiting in January, March and May.

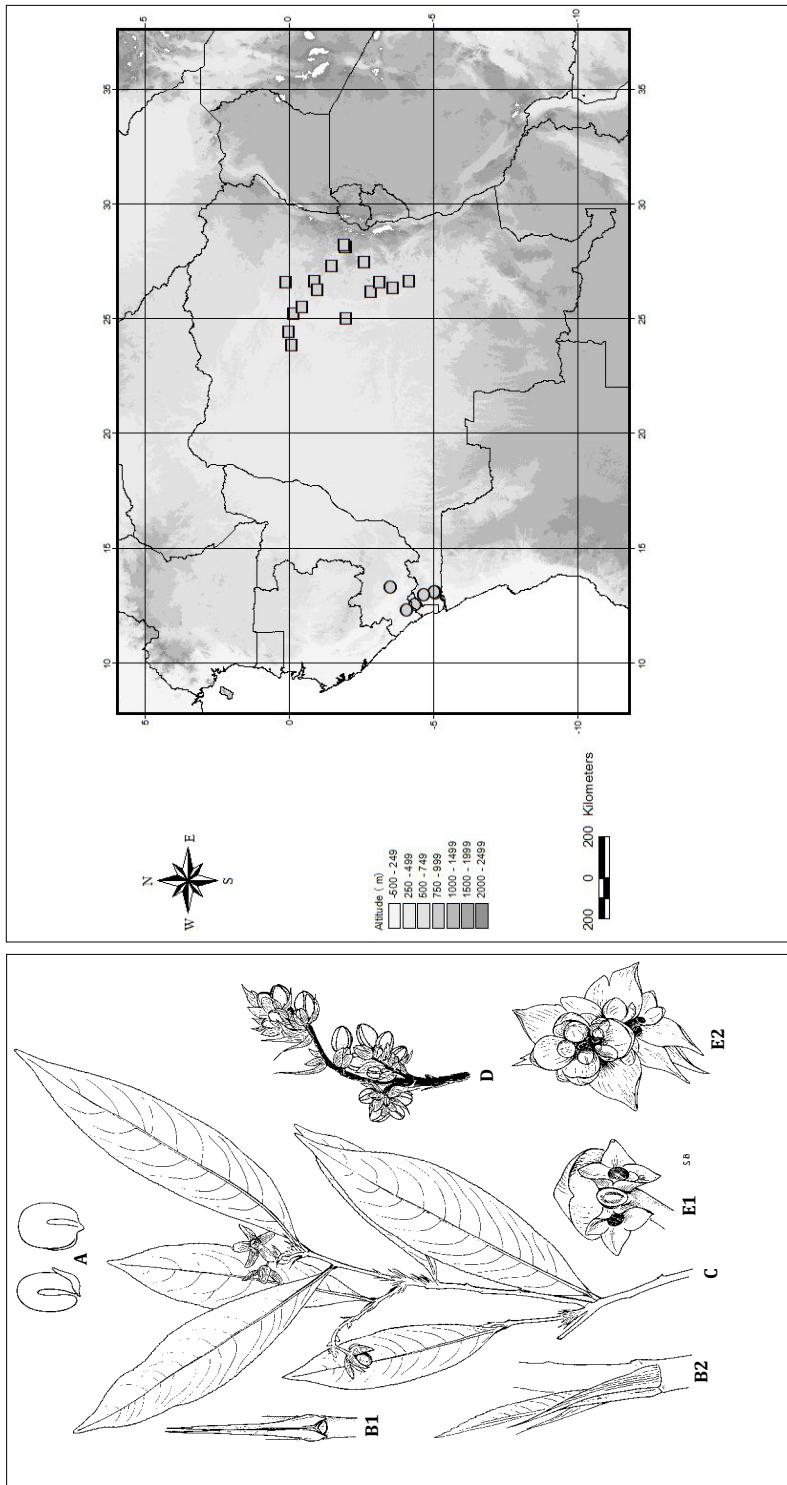

Figure 2. *Campylospermum cabrae*. **A.** Incumbent cotyledons, with small outer cotyledon. **B1 & B2.** stipules. **C.** Flowering branch. **D.** Inflorescence in fruit. **E1 & E2.** Receptacle with persistent sepals. Drawings by Sabine Bousani
Map 4. Distribution of *Campylospermum cabrae* (○) and *Campylospermum claessensii* (□)

Vernacular names: Democratic Republic of the Congo: Luvamba (Luki).

IUCN conservation status: EN B1/B2ab(iv). EOO=11,573 km², AOO=2,408 km², locations=7, subpopulations=2 (cell width=22 km). This species is known from only 8 specimens, collected between 1897 and 1966 and hence its present-day presence needs confirmation. On top of that, none of the older records are from within presently protected areas. Thus, the category Endangered seems justified.

Specimens examined:

ANGOLA, Cabinda: Mayombe, buco Zau. 4°45'S, 12°34'E, October 1916 (fl), *Gossweiler* 7193 (BM, COI, LISC).

***Campylospermum calanthum* (Gilg) Farron**

Fig. 3

Bull. Jard. Bot. État Bruxelles 35: 394 (1965). – *Ouratea calantha* Gilg, Bot. Jahrb. Syst. 33: 259 (1904). – Type: *Zenker* 1845 (holotype: B†; isotype: HBG!, K!, P(2x)!), Cameroon, Bipindi, 1898.

Monelasmum zenkeri Tiegh., J. Bot. (Morot) 16: 200 (June 1902). – Type: *Zenker* 1845 (holotype: P(2x)!; isotype: HBG!, K!), Cameroon, Bipindi, 1898. (non *Campylospermum zenkeri* (Tiegh.) Farron ≡ *C. oliveri* (Tiegh.) Farron)

Monelasmum sibangense (Gilg) Tiegh., Ann. Sci. Nat., sér. 8, Bot, 18: 36 (June 1903). *Ouratea sibangensis* Gilg, Bot. Jahrb. Syst. 33: 267 (1904). – Type: *Soyaux* 53 (holotype: P!; isotype: K!), Gabon, Sibange Farm, January 22th, 1880. **syn. nov.**

Ouratea nigroviolacea Gilg ex Bak. in Rendle *et al.*, Cat. pl. Oban: 124 (1913). -Type: *Talbot* 1282 (holotype: K!), Nigeria, Oban.

Tree up to 10 m tall, with branched stem; twigs with dark brown coloured bark. Stipules persistent, narrowly to very narrowly triangular, 4–12(–25) mm long. Leaf: petiole 2–10 mm long, stout, canaliculate above; leaf blade elliptic to elliptic-obovate or rarely obovate or narrowly elliptic-obovate, (8-)17–20(-37.5) x (3.5-)6–10(-12.5) cm, ratio (2.25-)3-4, base generally cuneate or sometimes attenuate, rarely rounded, apex acuminate or rarely acute, coriaceous, slightly to distinctly bullate, upper side green, glossy, lower side paler green, dull, margin serrulate, sometimes shallowly so, or rarely entire; venation: midrib flattened on upper side, prominent on lower side, main lateral veins 13–22 on either side, (7-)10–20(-30) mm apart, flat to slightly prominent on both sides, more or less at a right angle with the midrib but curved upward to run parallel to the margin, intermediate lateral veins 1–3 in between each pair of main lateral veins, slightly sunken on upper side, prominent on lower side, tertiary venation scalariform, perpendicular to the midrib, indistinct on upper side,

fairly distinct on lower. *Inflorescence* terminal, branched, lax; **pairwise scales at the base of peduncle persistent, sometimes leafy**, 15–20(–30) x 4–10 mm, its main axis (8–)15–35(–38) cm long; racemes 2–7, slender, (5–)8–19(–23) cm long, **ascendant or rarely held horizontally**; bracts **persistent**, triangular, 3–15(–30) mm long; cymules 0.5–2 cm apart, 1–6(–15)-flowered. *Flower*: pedicel 5–9 mm, articulated at 2–4 mm from the base; sepals ovate, in flower 6–8 x 3–4 mm, in fruit 7–10 x 4–6 mm, base truncate, apex acute to rounded; petals **obovate**, 3–9 x 3–6 mm, **truncate at base, rounded to slightly emarginate at apex**; stamens: anthers 5–6 mm long; ovary 1–2 mm long; style 4–5 mm long. *Fruit*: receptacle c. 1 mm thick in flower, in fruit 4–6 x 4–5 mm; drupelets 1–4 well developed per receptacle, **reniform**, slightly compressed, 8–11 x 6–8 mm; cotyledons **accumbent, ± similar in size**.

Notes: *C. calanthum* is sometimes difficult to tell apart from *C. dybovskii*. The former generally has much broader leaf blades with lateral veins prominent below, but some *C. calanthum* specimens may have fairly narrow leaf blades while some *C. dybovskii* specimens may have lateral veins that are slightly prominent below. In those cases, *C. calanthum* can be recognized by its persistent stipules and slightly to distinctly bullate leaves (caducous stipules and non-bullate leaves in *C. dybovskii*).

Distribution: south-eastern Guinea, southern Liberia, Ivory Coast to Ghana, Nigeria, Cameroon, Central African Republic, Equatorial Guinea, Gabon, Republic of the Congo, Democratic Republic of the Congo and Angola (Cabinda) (**Map 5**).

Ecology: in primary, secondary, high, dense gallery forest, coastal, littoral wet and swamp forest, forest edges, along rivers; on brown, sandy soil and brown reddish clay; at up to 1100 m altitude.

Phenology: flowering and fruiting all year round.

IUCN conservation status: LC B1/B2ab(i,ii,iii). EOO=3,265,430 km², AOO=3,473,140 km², locations=247 (cell width= 389 km). This species is quite well represented in herbaria, which seems to indicate it is not uncommon in the wild, and occurs from West Africa all the way down to Angola (Cabinda) and is found in a wide variety of habitats. Therefore, the category of Least Concern seems most appropriate.

Key literature: Bamps & Farron (1967), Cheek (2004), Exell & Mendonça (1951), Farron (1963, 1985), Friis & Vollesen (1998), Hawthorne & Jongkind (2006).

***Campylospermum claessensii* (De Wild.) Farron**

Fig. 4

Bull. Jard. Bot. État Bruxelles 35: 394 (1965). – *Ouratea claessensii* De Wild., Pl. Bequaert. 4: 450 (1928). – Lectotype (designated here): *Claessens 338* (BR!; isotype: BR!), Democratic Republic of the Congo, Batama, March 1921.

Treelet up to 4 m tall, with branched stem; twigs with pale coloured bark. *Stipules* caducous, narrowly triangular, 3–7 mm long. *Leaf*: petiole 3–10 mm long; leaf blade **narrowly elliptic-obovate** to elliptic-obovate, **11–25 x 3.5–9 cm**, ratio **2–3**, base cuneate, apex acuminate, coriaceous, bullate, upper side medium green, lower side paler green, ± glossy on both sides, margin serrulate; venation: midrib prominent on upper side, strongly prominent on lower side, main lateral veins 12–17 on either side, 8–22 mm apart, **shallowly sunken on upper side, prominent on lower side**, at a **right to oblique angle with the midrib** but curved upward to run parallel to the margin, intermediate lateral veins **0–3 in between each pair of main lateral veins**, sunken on upper side and prominent on lower sides, tertiary venation scalariform, perpendicular to the midrib, **fairly distinct on upper side, distinct on lower**. *Inflorescence* terminal, branched or sometimes unbranched, **robust, lax**, its main axis 21–26(–31) cm long; pairwise scales at the base of peduncle **persistent**; racemes, 0–3, 10–17(–29) cm long, **ascendant; bracts persistent, triangular, 2–4 mm long; cymules 0.5–2 cm apart, 1–20-flowered**. *Flower*: pedicel 8–12 mm long, articulated at 1–2 mm from the base; sepals ovate, in flower 4–6 x 2–3 mm, in fruit 5–10 x 3–4 mm, first patent then erecto-patent; petals **obovate, 9–10 x 5–7 mm, clawed at base**, rounded at apex; stamens: anthers 4–5 mm long; ovary 1–2 mm long; style 4–5 cm long. *Fruit*: receptacle enlarged to 3–5 mm wide; drupelets **broadly ellipsoid**, 7–8 x 5–6 mm; cotyledons **incumbent, dissimilar in size, with a small outer cotyledon**.

Notes: The protologue cites two syntypes, one collected by Claessens and one by Bequaert. It seems logic, in line with the etymology, to choose the first one as the lectotype. *C. claessensii* is close to *C. gabonense* by having obovate leaves with shallowly sunken main lateral veins, persistent pairwise scales at the base of the peduncle and persistent bracts. However, *C. claessensii* differs from *C. gabonense* by having a much longer and more lax inflorescence, pedicels articulating at only 1–2 mm from the base as well as caducous and smaller stipules.

Distribution: endemic to the eastern half of the Democratic Republic of the Congo (Maniema, North Kivu, South Kivu and Orientale provinces) (**Map 4**).

Ecology: in high primary and secondary forest, swamp forest; at 470–800 m altitude.

Phenology: flowers observed in all months except for February and May; fruits observed in March, June, October and December.

Vernacular names: Democratic Republic of the Congo: Kashindabakoi (lega).

IUCN conservation status: LC B1/B2ab(i,ii,iv). EOO=148,609 km², AOO=65,699 km², locations=17, subpopulations=2 (cell width= 64 km). This species is only known from 18 collections, the most recent one is from 1989, and some collections fall into two protected areas (Maiko NP and collaborative Fishery Management Area). Thus, although endemic to the eastern Democratic Republic of the Congo, it does not seem to be under severe threat and the category of Least Concern seems most appropriate.

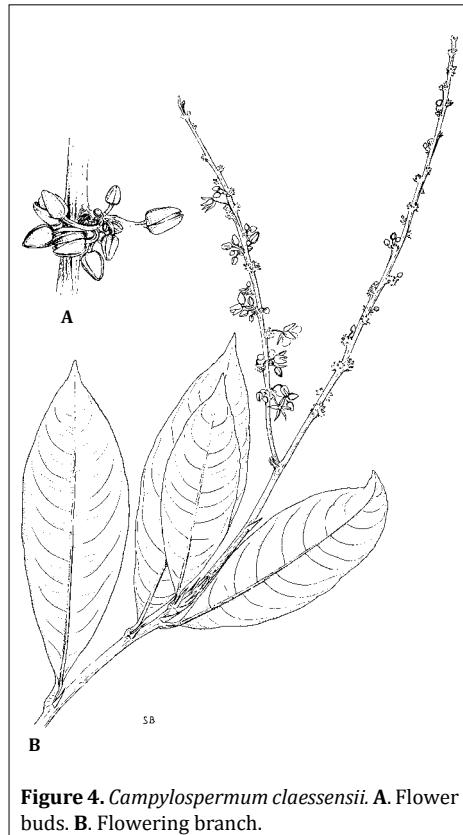

Figure 4. *Campylospermum claessensii*. A. Flower buds. B. Flowering branch.

***Campylospermum congestum* (Oliv.) Farron**

Bull. Jard. Bot. État Bruxelles 35: 394 (1965). – *Gomphia congesta* Oliv., Fl. trop. Afr. 1: 322 (1868). – *Ouratea congesta* (Oliv.) Engl. ex Gilg in Engl. & Prantl., Nat. Pflanzenfam. ed. 1, III, 6: 142 (1893). – *Exomicrum congestum* (Oliv.) Tiegh., Ann. Sci. Nat., Bot. 16: 338 (1902). – Type: Mann s.n (holotype: K!), Sierra Leone.

Treelet up to 2 m tall, with branched trunk, twigs with brown coloured bark. ***Stipules persistent***, triangular to narrowly triangular, 2–6 mm long. ***Leaf***: petiole 3–8 mm long; leaf blade **elliptic or elliptic-ovate to narrowly elliptic**, 6–20(–25) x (2–)3–6(–8) cm, ratio **(2–)3–4**, **base cuneate, apex acute to acuminate**, coriaceous, slightly bullate, margin **serrulate** but entire towards the base, upper side medium green, lower side paler green; midrib **prominent on upper side, flattened beneath**, main lateral veins **12–20** on either side, **5–20 mm apart**, prominent on upper side, **flat to shallowly impressed beneath, at a slightly acute to right angle with the midrib** but curved upward to the margin, intermediate lateral veins 1–3 in between each pair of main lateral veins, less prominent, tertiary venation **scalariform, consisting of very fine and parallel veins**, distinct to slightly so above, slightly distinct below. ***Inflorescence*** terminal, **compact, unbranched or occasionally with a few short racemes at the base**, its main axis 3–12(–15) cm long; **racemes 0(–2), 1–2 cm long**; pairwise scales at the base of the peduncle persistent, triangular, 3–5 mm long; bracts caducous; cymules **0.5–1 cm apart, 2–6-flowered**. ***Flower***: pedicel **4–11 mm, articulated at the very base**; sepals ovate, in flower 4–6 x 2–3 mm, in fruit 5–7 x 3 mm and patent to erecto-patent, base rounded, apex obtuse; petals obovate to broadly spatulate, **5–10 x 4–8 mm, rounded at apex**; stamens: anthers 3–5 mm long; ovary c. 1 x 1 mm; style 5–6 mm long. ***Fruit***: receptacle c. 2 x 1 mm in flower, c. 3 x 2 mm in fruit; drupelets 1–3 well developed per receptacle, **globose**, 5–6 x 5–6 mm; cotyledons **incumbent, ± similar in size**.

Notes: The leaves of this species are quite reminiscent of those of *C. squamosum* by looking at the serrulate margin and prominent main laterals on the upper side. However, its compact, short and often simple inflorescence readily distinguishes it from the latter which has lax, long and a much-branched inflorescence. Moreover, in *C. squamosum* the tertiary venation is more distinct and even prominent on the lower surface, while the pedicel is articulated well above the base. See also the note under *C. squamosum*.

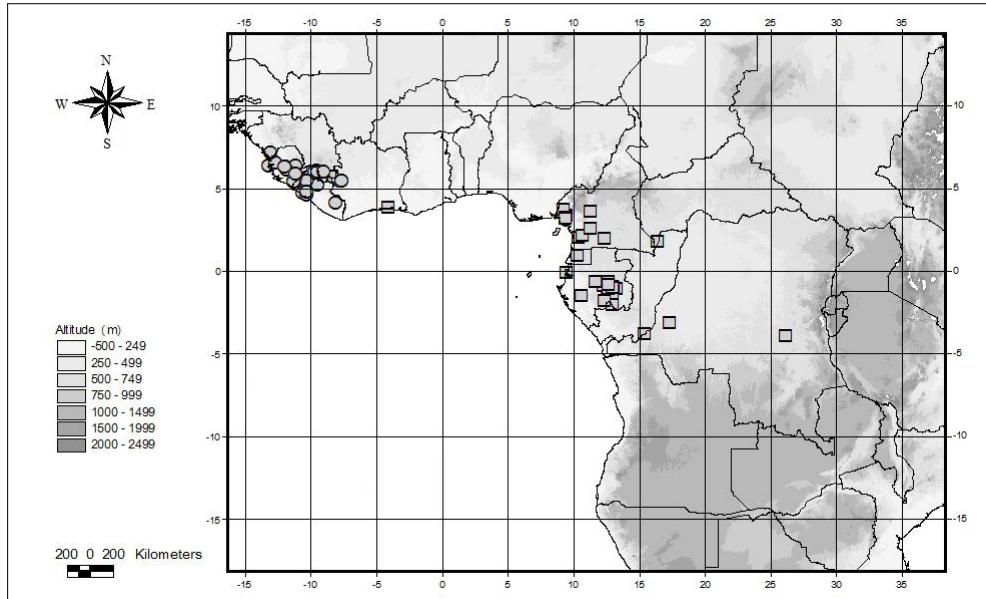

Distribution: West Africa, from Guinea to western Ivory Coast (**Map 6**).

Ecology: in primary and secondary, high, disturbed forest, along streams; at 15–1248 m altitude.

Phenology: flowering all year except for June and July; fruits collected from January to May and in September.

Uses: The Mende people of Sierra Leone crush the leaves and then put it on the cut of a palm that has just been tapped to keep off bees who would otherwise drink the palm-sap (Burkill, 1997).

IUCN conservation status: LC B1/B2(iii,iv). EOO=118,981 km², AOO=89,629 km², locations=33, subpopulations=9 (cell width=69 km). This species seems to have a scattered occurrence while some subpopulations occur in Forest Reserves such as Sangouine (Ivory Coast), Kpelle (Liberia), Lorma (Liberia) and Mont Tonkoui (Guinea). Therefore, the category of Least Concern has been assigned.

Campylospermum costatum (Tiegh.) Biss.

Fig. 5

Blumea 58: 6 (2013). – *Monelasmum costatum* Tiegh., Ann. Sci. Nat., ser. 8, Bot., 16: 333 (1902). – *Campylospermum vogelii* (Hook.f.) var. *costatum* (Tiegh.) Farron, Bull. Jard. Bot. État Bruxelles 35: 403 (1965). – Type: Zenker 1762 (holotype: P(2x)!; isotype: B!, COI!, G!, K!, L!, LY!, S!, WAG(2x)!), Cameroon, Bipinde, 1898.

Ouratea bracteata Gilg, Bot. Jahrb. Syst. 33: 264 (1904). – Type: Staudt 161 (holotype: B†; isotype: BR(x2)!, E!, P!), Cameroon, Lolodorf.

Tree up to 6 m tall, with branched trunk; twigs with pale coloured bark. **Stipules persistent to caducous**, triangular to narrowly so, 4–10 mm long. **Leaf:** petiole 3–7 mm long, **stout**; leaf blade **narrowly elliptic to narrowly obovate**, (11–)14–35(–46) x (4–)6–12(–15) cm, ratio 3–3.5, base **cuneate to rounded**, apex acute to acuminate, **coriaceous**, not bullate, margin **regularly serrate**, **teeth with a dark tip**, upper side glossy, dark green, lower side glossy, medium green; midrib prominent on both sides, main lateral veins 10–25 on either side, 10–20(–40) mm apart, more or less at a right angle with the midrib but curved upward, prominent on both sides, intermediate lateral veins 1 to 2 in between each pair of main laterals, prominent on both sides, tertiary venation **scalariform to reticulate, distinct on both sides**. *Inflorescence* terminal, **on top of a very robust flattened twig, branched, lax to fairly dense**, its main axis **(4–)5–18 cm long; racemes 3–6, (2–)6–7(–13) cm long, the axes flattened**; pairwise scales present at the base of the peduncle, triangular; bracts caducous, ovate, 1.5–4 mm long; cymules **0.5–2 cm apart**, 3–7-flowered. *Flower:* **pedicel 3–7 mm long, stout**, articulated at **1–2 mm from the base**; sepals narrowly ovate, in flower 7–8 x 2–4 mm, in fruit up to 10 x 5 mm and erecto-patent, base **rounded**, apex **acute**; petals **obovate, 7–9 x 4–5 mm, cuneate** at base, **rounded** at apex; stamens: anthers 4–6 mm long; ovary c. 1 mm long; style 4–6 mm long, *Fruit:* receptacle 4–6 mm wide; drupelets 3–5 well developed per receptacle, globose to broadly ellipsoid, c. 6–8 x 5–7 mm; **cotyledons**

incumbent, dissimilar in size, with a small outer cotyledon.

Notes: *C. costatum* was judged to be a mere variety of *C. vogelii* by Farron (1965, 1985), but we found sufficient characters to raise it to species level. It mainly differs from *C. vogelii* by often having longer and broader leaves, a stout petiole, an inflorescence sitting on top of a robust and flattened twig and often shorter and stout pedicels.

Distribution: Ivory Coast? (only one doubtful collection), Central African Republic (Sangha-Mbaéré), Cameroon, Equatorial Guinea, Gabon, Republic of the Congo and Democratic Republic of the Congo ([Map 6](#)).

Ecology: secondary forest, degraded and exploited forest; at 100–700 m altitude.

Phenology: flowering in March, April, and from September to November; fruiting from March to May, and in October and November.

IUCN conservation status: LC. EOO=1,584,220 km², AOO=1,366,610 km², locations=34 (cell width=352 km). With the doubtful outlier specimen from Ivory Coast excluded, these figures are EOO=553,852, AOO=203,063, locations=29 (cell width=124.981). Although some populations might well be under threat (notably the large one around Lastoursville (Gabon), where logging companies operate), its preference for secondary habitats probably renders it less susceptible to logging. Even around Lastoursville, it was still present in 2009 and, moreover, it has a large distribution area. Thus, the category of Least Concern seems most appropriate here.

Ouratea coriacea De Wild. & T.Durand, Ann. Mus. Congo, Bot., ser. 3, 1: 36 (1901). –

Exomicrum coriaceum (De Wild. & T.Durand) Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 338 (1902). – Type: *Dewèvre* 795 (holotype: BR!; isotype: BR!), Democratic Republic of the Congo, entre Lukolela et Gombe, February 17th, 1896.

Exomicrum grandifolium Tiegh., Ann. Sci. Nat., sér. 9, Bot. 5: 172 (June 1907). – Type: *Chevalier* 6922 (holotype: P!), Tchad, Ndellé, territoire du Chari, December 25th, 1902.

Monelasmum coriaceum Tiegh., Ann. Sci. Nat., sér. 9, Bot. 5: 171 (June 1907). – *Gomphia coriacea* (Tiegh.) Lye, Lidia 4(3): 91(1998). – Type: *Chevalier* 7318 (holotype: P!), Tchad, Mbélé, territoire du Chari, January 20th, 1903.

Ouratea laevis De Wild. & T.Durand var. *ipamuensis* De Wild., Pl. Bequaert. 4: 482 (1929).

– Lectotype (designated here): *Vanderyst* 10997 (BR!), Democratic Republic of the Congo, Ipamu, August 1921.

Campylospermum katangense Farron, Bull. Jard. Bot. État Bruxelles 35: 397 (1965). – Type: *Young* 127a (holotype: BM!; isotype: BR!), Democratic Republic of the Congo, Katanga (Shaba), Dilolo, July 20th, 1932. **syn. nov.**

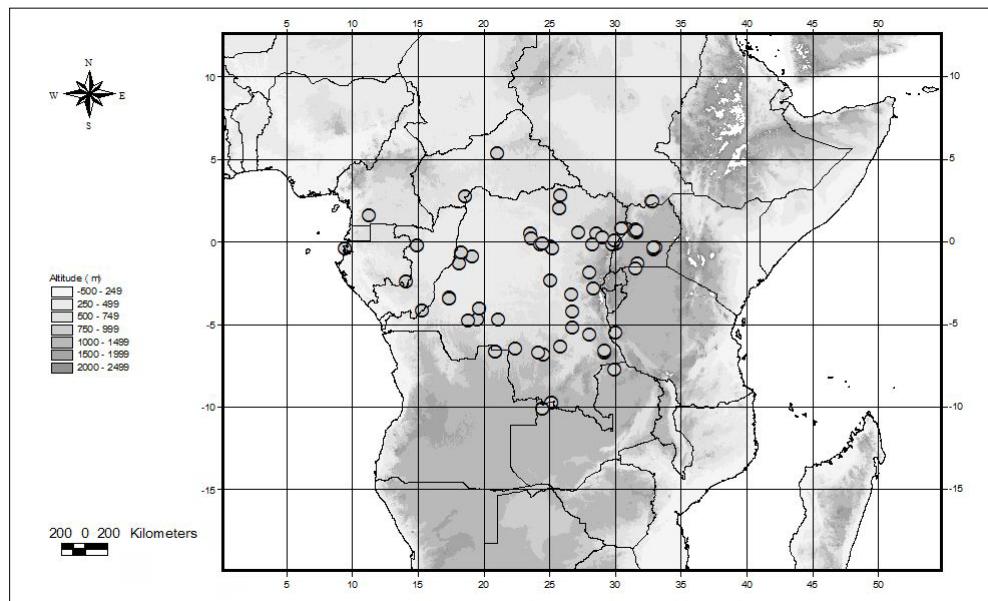

Tree, erect or rarely scandent, **up to 20 m tall**; **bole up to 8 cm in diameter**, with branched trunk; twigs with dark coloured bark. *Stipules* caducous, triangular, **(2-)4-9 mm long**. *Leaf*: **petiole 5-12 mm long**, stout; leaf blade **narrowly elliptic to narrowly elliptic-obovate or sometimes elliptic-obovate**, **(10-)19-32(-36) x (2.5-)7-9(-12) cm**, ratio **2-3(-4)**, base rounded to cuneate, apex blunt to acuminate, coriaceous, not bullate, glossy above, slightly glossy below, margin regularly serrulate; venation: midrib flat to ± **canaliculate towards the base above**, prominent beneath, main lateral veins **10-15** on either side, **10-40 mm apart**, mostly **indistinct above**, **distinct on the lower side**, at a ± right angle with the midrib, curved upwards to run parallel to the margin, intermediate lateral veins 1-5, distinct on the lower side, tertiary venation **scalariform**, **indistinct above**, slightly distinct to distinct below. *Inflorescence* terminal or sometimes axillary, branched, fairly lax its main axis **(5-)10-26(-32) cm long**, **more or less angular**, robust; **racemes 2-7, (3-)6-23(-30) cm long**, **ascendant**; pairwise scales **caducous**; bracts caducous, sometimes leafy, elliptic, **5-8 x 2-3 cm**; cymules **0.5-1 cm apart**, **1-9(-16)-flowered**. *Flower*: pedicel **7-15 mm**, **articulated at (2-)4-5(-7) mm from the base**; sepals ovate to elliptic, **6-7 x 3-4 mm** in flower, **8-11 x 4-5 mm** in fruit, erecto-patent; petals obovate, **6-11 x 4-8 mm**, **base without or with a broad claw**, apex rounded; stamens: anthers **4-6 mm long**; ovary c. **1 x 1 mm**; style **5-7 mm long**. *Fruit*: receptacle c. **1 mm thick** in flower, **6 x 5 mm** in fruit; drupelets **3 to 4 well developed per receptacle**, **ellipsoid**, **7-10 x 4-6 mm**; cotyledons **incumbent**, **dissimilar in size with a small outer cotyledon**.

Notes: *C. densiflorum* is similar to *C. dybovskii*, but differs by having a distinct though not or slightly prominent main lateral veins on the lower leaf surface. It also differs from *C. dybovskii* by its highly branched inflorescence having an angular peduncle.

The material described as *C. katangense* only differs from *C. densiflorum* by its smaller

leaves and reduced inflorescence. It is here regarded as a depauperate form of the latter. The material cited by De Wildeman (1929) under his new variety *ipamuensis* (within *Ouratea laevis*) belongs to three different species (*C. densiflorum*, *C. dybovskii* and *C. plicatum*, see also Farron, 1967). By choosing a lectotype here, we solved this situation, and sink the name into the synonymy of the first.

Distribution: Cameroon, Central African Republic, Equatorial Guinea, Gabon, Democratic Republic of the Congo, north-eastern Angola, southern Sudan, Uganda, Kenya, Burundi, Tanzania and northern Zambia (**Map 7**).

Map 7. Distribution of *Campylospermum densiflorum*

Ecology: in primary and secondary rain forest, dry and gallery forest, savannah and montane forest, seasonal swamp forest, along rivers and streams, near waterfalls; on yellow-brown or grey clay soil; at 300-2000 m altitude.

Phenology: flowering and fruiting all year round.

IUCN conservation status: LC B1/B2(i,ii). EOO=4,031,040 km², AOO=3,965,950 km², locations=184 (cell width=282 km). The species is well represented in herbaria (we studied 253 collections) suggesting it is fairly common. It has been collected in various protected areas such as Odzala National Park (Republic of the Congo), Loango National Park and Plateaux Batéké (Gabon), Dzanga-Sangha National Park (Central African Republic), Virunga National Park (Democratic Republic of the Congo), Budongo Forest Reserve (Uganda), etc. Therefore, the category of Least Concern seems most appropriate.

***Campylospermum descoingsii* Farron**

Fig. 6

Bull. Jard. Bot. État Bruxelles 35: 395 (1965). – Type: *Farron 4021* (holotype: P!, isotype: P(2x)!, IEC), Republic of the Congo, îlot forestier sur le Congo, à hauteur de Moutampa, March 1965.

Treelet up to 4 m tall, with branched trunk, twigs with pale brown coloured bark. ***Stipules persistent***, triangular, 2–7 mm long. ***Leaf***: petiole 2–5 mm long; ***leaf blade narrowly elliptic to narrowly elliptic-obovate, (9-)12-25(-27) x (3-)4-5(-7) cm***, ratio 3–4, base cuneate to rounded, apex acuminate, ***papyraceous, bullate between the lateral veins, margin serrulate to entire***, upper side slightly dull dark green, lower side dull medium green; venation: midrib ± flattened on the upper side, prominent on the lower, ***main lateral veins 10–19 on either side, 5–15 mm apart, prominent but sunken in the bullae above, prominent below***, at a more or less right angle with the midrib but curved upwards toward the margin, intermediate lateral veins prominent on both sides, tertiary venation ***scalariform, perpendicular to the midrib***, distinct on both sides. ***Inflorescence*** terminal, composed of ***1–3 long racemes sitting close together on the twig, pendulous;*** their main axis 11–19 cm long; ***pairwise scales at the base of peduncle persistent; bracts persistent, triangular, 1–2 mm long;*** cymules 0.3–1 cm apart, 1–5-flowered. ***Flower***: pedicel 4–5 mm long, articulated at c. 1 mm from the base; sepals ovate to elliptic, in flower c. 3–4 x 2 mm, in fruit 5 x 3 mm; petals obovate, 5–7 x 2–5 mm, base rounded, apex slightly emarginate; stamens: anthers slender, 3–4 mm long; style 3–4 mm. ***Fruit***: receptacle c. 1 mm thick in flower, in fruit 3–4 mm; drupelets ***1–2 well developed per receptacle, ellipsoid, more or less compressed; cotyledons accumbent, similar in size.***

Notes: This species is mainly characterized by its bullate upper leaf surface. It is close to *C. excavatum* by having a distinct tertiary venation. However, it differs by having an unbranched inflorescence composed of 1–3 racemes sitting close together terminal on the twig, whereas *C. excavatum* has a branched inflorescence.

Distribution: Republic of the Congo (province of Pool) and Democratic Republic of Congo (province of Bas-Congo) (**Map 8**).

Ecology: in high and secondary forest.

Phenology: flowering from November to December and in January and March; fruits observed in January, March and May.

IUCN conservation status: CE B1/B2 (i,ii). EOO=712 km², AOO=305 km², locations=8, subpopulations=4 (cell width= 7 km). This species is only known from 11 collections, all outside of protected areas. Its last collection dates back to 1968, thus its present occurrence needs to be confirmed. Therefore, the category of Critically Endangered has been assigned.

Campylospermum duparquetianum* (Baill.) Tiegh.*Fig. 7**

J. Bot. (Morot) 16: 43 (1902). – *Gomphia duparquetiana* Baill., Adansonia 9: 77 (1868). – *Ouratea duparquetiana* (Baill.) Gilg, Bot. Jahrb. Syst. 33: 258 (1904). – Type: *Duparquet 60* (holotype: P!), Gabon, December 1862.

Ouratea corymbosa Engl., Bot. Jahrb. Syst. 17: 80 (1893). – Type: *Soyaux 40* (holotype: B†; isotypes: K!, P!, Z!), Gabon, Munda, Sibang Farm, 1879.

Ouratea cameronii Hutch. & Dalziel, Fl. W. trop. Afr., ed. 1, 1: 193 (1927). – Type: *Burton & Cameron* s.n. (holotype: K!), Ghana, Axim.

Treelet up to 8 m tall, monocaulous bark dark brown. **Stipules** caducous, triangular, 3–5 mm long. **Leaves** all grouped at the top of the stem; petiole 0–10 mm long; leaf blade **narrowly spatulate to narrowly elliptic-spathulate, 26–49(–58) x 5–12(–17) cm**, ratio 3–5(–6.23) base broadly cuneate to rounded or slightly cordate, apex acute to slightly acuminate, coriaceous to papery, not to slightly bullate, margin regularly serrate, upper side dark green, glossy, lower side light green, dull; venation: midrib prominent on both sides, main lateral veins 20–30 on either side, 7–35 mm apart, making a slight angle with the midrib and slightly curved upward, prominent but running often through a gully above, prominent below, with 0–2 intermediate lateral veins in between subsequent main ones, tertiary venation **scalariform, running perpendicular to the main lateral veins**, indistinct to slightly distinct above, distinct below. **Inflorescence axillary, corymbose**; peduncle cylindrical, **woody**, 2–5(–6) cm long, with many short racemes of up to 1.5 cm long and (4–)20–35 **solitary** flowers, with **2 to 4 leafy bracts in its apical part; pairwise scales 4–8 mm long, persistent** at the base of peduncle; bracts triangular, 1–2 mm long. **Flower:** pedicel **10–50 mm long**, articulated at **4–8 mm** from its base; sepals narrowly ovate, in flower 7–11 x 3 mm, orange green, in fruit 15–20 x 6–8 mm, red; petals obovate, 16–18 x 4–8 mm, **shortly clawed at base, slightly emarginate at apex**; stamens: **anthers 6–7 mm long**; ovary more or less flattened, 2–3 mm long; style c. 7 mm long. **Fruit:** receptacle globose, 5 x 6 mm; drupelets 2–4 well developed per receptacle, **ovoid**, 9–10 x 5–7 mm; cotyledons **incumbent**, more or less **similar in size**.

Notes: A very distinct species belonging to a small group of monocaulous species with similarly large and narrowly spatulate to narrowly elliptic-spatulate leaves. However, its short and corymbose inflorescence renders this species very different from the others.

Distribution: from Liberia to Ghana and in Cameroon, Equatorial Guinea and Gabon (Map 8).

Ecology: in primary and secondary rain forest, sometimes in disturbed forest along forestry roads, in dried swamps, and riverine forest; on sandy clay soil; at 10–410 m altitude.

Phenology: flowers observed in all months except for August; fruits observed in all months except for the period July to October.

Uses: The plant is occasionally planted as an ornamental.

IUCN conservation status: LC B1/B2(i,ii). EOO=841,579 km², AOO=512,109 km², locations=75 (cell width= 238 km). A species with a disjunct but fairly wide distribution occurring in National Parks such as Moukalaba-Doudou and Pongara in Gabon, Monte ALEN in Equatorial Guinea, Sapo in Liberia, and Taï in Ivory Coast. Therefore, the category of Least Concerned has been designated.

Campylospermum dybovskii Tiegh.

Fig. 8

Ann. Sci. Nat., sér. 8, Bot. 16: 298 (Dec. 1902). – *Ouratea dybovskii* (Tiegh.) Aké Assi, Candollea 55(2): 281 (2000). – Type: *Dybovski 139* (holotype: PI!), Gabon, Cap Lopez, February 17th, 1894.

Ouratea gentilii De Wild., Rev. Zool. Afr., Bot. 7: B53 (1920). – Type: *Gentil 33* (holotype: BR!; isotype: BR(x4)!), Democratic Republic of the Congo, bord des eaux, vallée de la Loange (Lualaba-Kasai), January 5th, 1902.

Ouratea latepaniculata De Wild., Rev. Zool. Afr., Bot. 7: B56 (1920). – Type: *Laurent 1153* (holotype: BR!), Democratic Republic of the Congo, Eala, July 1st, 1905.

Ouratea malelaensis De Wild., Pl. Bequaert. 4: 497 (1929). – Lectotype (designated here): *Vermoesen 1312* (holotype: BR!; isotype: K!, S!), Democratic Republic of the Congo, environs de Malela, 1909.

Tree up to 25 m tall; bole up to 13 cm in diameter, with multiple branches; twigs with dark coloured bark. **Stipules** caducous, leaving a conspicuous scar at the base of the petiole, triangular, c. 7 mm long. **Leaf:** petiole 2–10 mm long, stout, canaliculate above; leaf blade **narrowly elliptic to narrowly elliptic-obovate, (11-)16-32(-40) x (3-)5-8(-11) cm**, ratio 3–5, base cuneate to rounded, apex acute to acuminate, coriaceous, not bullate, upper surface green, glossy, lower surface paler green, margin **entire** or shallowly serrulate towards the apex; venation: midrib flattened to slightly prominent above, prominent beneath, **main lateral veins 9-19(-26) on either side, 7-17 mm apart**, not to slightly prominent above, prominent below, more or less at a right angle with the midrib but curved upward to run parallel to the margin, intermediate lateral veins **1 to 2** in between each pair of main laterals, **tertiary venation scalariform**, perpendicular to the main laterals or to the midrib, **indistinct above, distinct below**. **Inflorescence** terminal, lax, its main axis 12–30(–40) cm long, **generally in a zig-zag shape; pairwise scales at the base of the peduncle absent**; racemes 2–7, generally held horizontal, **11-19(-27) cm long**, occasionally these branched again; bracts **caducous**, sometimes a reduced leaf present at the base of peduncle, elliptic, 3–6 x

0.5–2 cm; cymules **0.5–3 cm apart, 1–4(–7)-flowered.** *Flower:* pedicel **5–12 mm long**, articulated at 1–4 mm from the base; sepals narrowly ovate to narrowly elliptic, in flower (6–)7–8 x 2–4 mm, in fruit 12–13 x 5–8 mm, base **cuneate**, apex **rounded**, enclosing the drupelets, coriaceous; petals obovate, (8–)12–19 x (5–)6–8 mm, **truncate at base, rounded at apex**; stamens: anthers 5–6 mm long; ovary c. 1–2 mm long; style 4–5 mm long, curved. *Fruit:* receptacle c. 1 mm long in flower, in fruit 4 x 5 mm; drupelets 1–5 well developed per receptacle, broadly reniform, 7–8 x 6–7 mm; cotyledons **accumbent, similar in size.**

Notes: This species is very close to *C. calanthum* and *C. densiflorum* (see the note under *C. densiflorum*). Its leaves differ by having a cuneate to rounded base and being narrowly elliptic to narrowly elliptic-obovate. Its main lateral veins are prominent while those of *C. calanthum* are sunken. The racemes are held horizontally whereas in *C. calanthum* they are ascending. However, exceptionally specimens of *C. dybowskii* may be encountered specimens that have a distinctly acuminate apex and marked secondary nerves that are not prominent on the upper side. Furthermore, some show a lax inflorescence with ascending racemes as in *C. calanthum*. Those specimens were formerly assigned to *O. malelaensis* and *O. latepaniculata*, but we follow Farron (1963) in regarding these as being conspecific with *C. dybowskii*.

Ouratea malelaensis was originally published with the citation of two syntypes: *Vermoesen* 1312 and 1222. *Vermoesen* 1312 has been designated as lectotype of *O. malelaensis* because this specimen is distributed in three herbaria and consists of fruiting material. Both sides of the leaf blade show the venation pattern character that is deemed important for the distinction with related species.

Campylospermum dybowskii Tiegh. was originally published as *C. dybowskii* by the French author Van Tieghem who named the plant after the plant collector M. Dybowski but he accidentally misspelled his family name. To be in accordance with the Code of Nomenclature, we regarded *C. dybowskii* as being an orthographic error and *C. dybowskii* is to be retained (ICBN Melbourne, Art. 60.1).

Distribution: Nigeria, Cameroon, Equatorial Guinea, Gabon, Republic of the Congo, Democratic Republic of the Congo and Angola (Zaire prov.) (**Map 9**).

Ecology: in primary or secondary forest, riverine forest, swampy and flooded forest; on laterite quarry, white and sandy soil; at 5–630 m altitude.

Phenology: flowering and fruiting all year round.

Uses: Roots are ground with seeds of *Aframomum melegueta* and eaten to remedy impotence (Neuwinger, 2000).

IUCN conservation status: LC B1/B2(i,ii,iv). EOO=2,112,090 km², AOO=1,811,660 km², locations=80 (cell width=259 km). This species has a wide distribution and is well represented in herbaria indicating it is not uncommon. Moreover, many of the collecting localities, at least in Gabon, are located inside National Parks (Moukalaba-Doudou,

Pflanzenfam., ed. 1, III, 6: 142 (Febr. 1893). – *Spongopyrena elongata* (Oliv.) Tiegh., Bull. Mus. Hist. Nat. (Paris) 8: 216 (Apr. 1902). – Type: *Mann* 77 (holotype: K!; isotype: E!), Equatorial Guinea, Ile Fernando-Po, 1859.

Spongopyrena cyanescens Tiegh., J. Bot. (Morot) 16: 201 (June 1902). – Type: *Soyaux* 179 (holotype: P!; isotype: K!, Z!), Gabon, Sibange-Farm, territoire de Munda, January 1881. *Spongopyrena reniformis* Tiegh., Ann. Sci. Nat. sér. 8, Bot. 16: 319 (1902). – Type: Zenker 975 (holotype: P!; isotype: BM!, G!, K!, S!, WAG!), Cameroon, Bipindi, 1896.

Treelet, up to 7 m tall, **monocaulous or rarely sparingly branched at the top**; bark brown. **Stipules** persistent, triangular, 8–10 mm long. **Leaves** clustered at the apex of the stem; petiole 5–8 mm long, **stout**; leaf blade **narrowly elliptic to narrowly obovate**, 18–61 x 4–15 cm, ratio **4–5(–7)**, base slightly cordate or sometimes rounded, apex acute to acuminate, papery to coriaceous, not bullate, margin **distantly serrulate, teeth with a dark tip**, upper side glossy dark green, lower side paler, fairly dull; venation: midrib flat and sunken on upper surface, **angular on the lower**, main lateral veins **20–35** on either side, **7–20(–30) mm apart**, slightly sunken on upper side, prominent on lower side, more or less at a right angle to the midrib but curved up towards the margin, intermediate lateral veins 1–3 in between each pair of main lateral, tertiary venation **scalariform, running more or less perpendicular to the main lateral veins**, distinct on both sides. **Inflorescence axillary, unbranched, fairly lax, pendant**, its main axis **distinctly flattened, 23–60(–83) cm long, 4–5 mm wide, without leafy bracts**, the part bearing flowers (5–)8–25 cm long; pairwise scales at the base of the peduncle persistent, **triangular, 6–11 mm long**; cymules 0.3–2.2 cm apart, 1–3(–6)-flowered; bracts tiny. **Flower**: pedicel 5–10 mm long, articulated at c. 1 mm from its base; sepals ovate to triangular, in flower 7–9 x 2–4 mm and green, in fruit up to 8–10 x 3–5 mm and red; petals elliptic, 7–9 x 3 mm, base cuneate, **apex acute**; stamens: anthers 5–7 mm long; ovary 2 mm high; style c. 6 mm long. **Fruit**: receptacle **up to 10(–12) mm wide**; drupelets 3–5 well developed per receptacle, **broadly reniform to almost globose**, 8–10 x 6–10 mm; **cotyledons accumbent, similar in size**.

Notes: A species easily recognized by its remarkably long and flattened peduncle. One specimen shows cymules elongated into short racemes, which is regarded as a rare mutation.

Map 10. Distribution of *Campylospermum elongatum*

Distribution: from Nigeria to Cameroon, southern Central African Republic, Equatorial Guinea, Gabon, Republic of the Congo, Angola (Cabinda) and the Democratic Republic of the Congo (**Map 10**).

Ecology: in primary and secondary forest, also in riverine or seasonally flooded rain forest; on sandy soil with humus; at 5–1150 m altitude.

Phenology: flowering and fruiting all year round.

Vernacular names: Democratic Republic of the Congo: Abé moro (Fang), Bololondgi (Lomongo), Edaka masese (Bila), Egbwapu/Bengia (Babua/Azandé), I Mbasá (Bakota), Kabesebese (Kinande), Kikusu (Dondolondo), Lengbalangwe Penza (Babua), Lifofa (Turumbu), Ndakamasese (Bila d'Epulu), Ngabi (Mitsogho), Olili Bo Kikereke, Gole, Gwanga, Mondondolindo.

IUCN conservation status: LC. EOO=2,654,780 km², AOO=2,803,160 km², locations=289 (cell width=291 km). A species widespread and fairly common in Central Africa. Therefore, the status of Least Concern seems most appropriate.

Key literature: Bamps & Farron (1967), Cheek et al. (2004), Exell & Mendonça (1951), Farron (1965, 1968, 1985), Hutchinson, Dalziel & Keay (1954).

Campylospermum engama* (De Wild.) Farron*Fig. 10**

Bull. Jard. Bot. État Bruxelles 35: 396 (1965). – *Ouratea engama* De Wild., Rev. Zool. Afr., Bot. 7: B48 (1920). – Lectotype (designated here): *Lemaire* 337 (holotype: BR!; isotype: BR!), Democratic Republic of the Congo, Mobwasa, June 1913.

Tree up to 11 m tall, with branched stem; twigs greenish. *Stipules* caducous, triangular, c. 2 mm long. *Leaf*: petiole **(5–)10–18(–25) mm long**; leaf blade narrowly elliptic to narrowly elliptic-oblong or ovate to obovate, (9–)16–25(–39) x (2.5–)4–7(–9) cm, ratio **3–4(–5.5)**, base typically attenuate, decurrent onto the petiole, apex acute to obtuse, sometimes mucronate, papyraceous, not bullate, upper side glossy, dark green, lower side dull, paler green, margin serrate all along, the teeth with a black tip; venation: midrib flattened above, prominent beneath, main lateral veins generally **12–19 on either side, 10–25(–35) mm apart**, prominent on both sides, at a right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins 1–5 in between each pair of main laterals, distinct on both sides, tertiary venation **scalariform**, more or less perpendicular to the midrib, joined by cross veinlet, distinct on both sides. *Inflorescence* terminal or sometimes axillary, branched, **lax**, its main axis (20–)25–33(–35) cm long, **more or less angular to flattened**; pairwise scales absent; bracts caducous; **racemes (3–)4–8, (3–)8–23(–40) cm long**, perpendicular to the main axis, **occasionally with secondary racemes**; cymules 1–2(–3) cm apart, 1–8(–11)-flowered. *Flower*: pedicel 5–10(–15) mm long, articulated at 1–5(–8) mm from the base; sepals ovate, 5–7 x 2–3 mm in flower, 8–10 x 3–5 mm in fruit; petals obovate, 7–10 x 3–6 mm, **base clawed, apex rounded**; stamens: anthers 4–7 mm long; ovary 1 mm high; style 5–7 mm long. *Fruit*: receptacle enlarged up to 6 x 5 mm; drupelets 3 to 4 well developed per receptacle, broadly **ellipsoid to globose**, 6–9 x 5–7 mm; cotyledons **incumbent, dissimilar in size with a small outer cotyledon**.

Notes: A lectotype has been designated from amongst the two syntypes available: *Lemaire* 337 and *De Giorgi* 737. Because the latter material could not be traced, we have chosen for *Lemaire* 337.

C. engama is sometimes closely resembling *C. laeve*, especially when the latter have inflorescences with long racemes, because both share a very long petiole. However, *C. laeve* can generally easily be distinguished by its thickened and often revolute leaf margin and markedly longer sepals (see also the note under *C. laeve*).

Distribution: Cameroon, southern Central African Republic (Sangha-Mbaéré province), Gabon, Republic of the Congo and Democratic Republic of the Congo (**Map 11**).

Ecology: in primary, secondary and understory forest, in dry and gallery forest; on sandy soil; at 100–620 m altitude.

Phenology: flowering from October to March, also in May and June; fruits observed in February, May, June, August and December.

Uses: The wood is used as timber (Farron 1967).

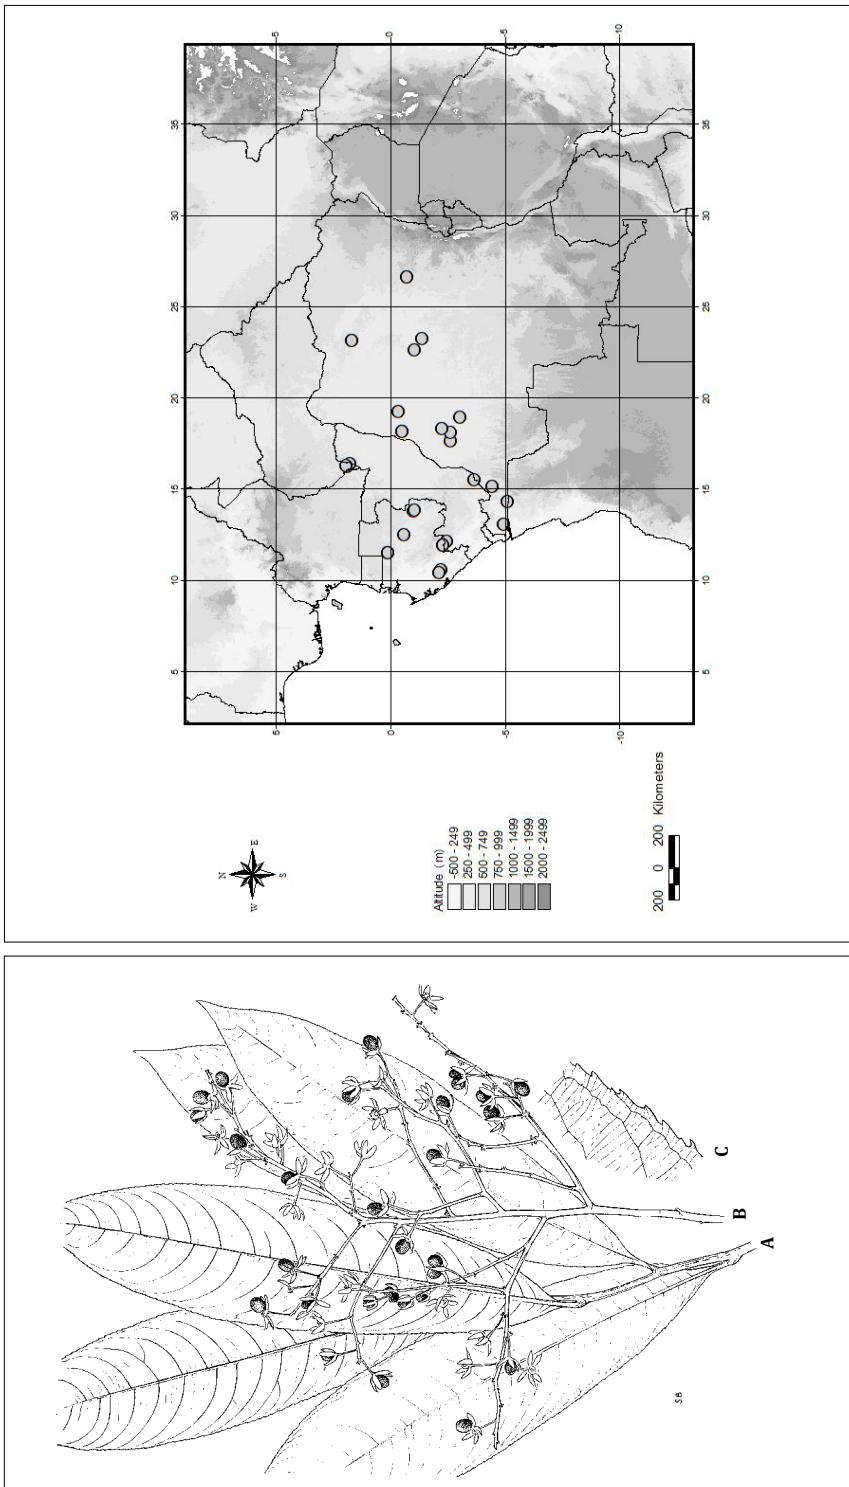

Figure 10. *Campylospermum engama*. A. Sterile branch. B. Fruiting branch. C. Leaf margin. Drawings by Sabine Bousani
Map 11. Distribution of *Campylospermum engama*

Vernacular names: Democratic Republic of Congo: Engama, Lengama (Mobwasa).

IUCN conservation status: LC. EOO=1,075,501 km², AOO=627,110 km², locations=27 (cell width=182 km). Although from the amount of herbarium collections this species appears to be fairly rare and to have a scattered occurrence, its area of occupancy is very large. Moreover, it is found inside National Parks such as the Lopé Reserve and Loango NP, both in Gabon, and the Dzanga-Sangha NP in the Central African Republic. Therefore, the category of Least Concern seems most appropriate.

Specimens examined:

CENTRAL AFRICAN REPUBLIC, Sangha-Mbaéré: Kongana research camp, 25 km SE of Bayanga., 2°55'N 16°16'E, 2 June 1994 (fl, fr), *Harris, D.J.* 5037 (E,WAG); Kongana research camp, 25 km SE of Bayanga. 2°47'N 16°25'E, 9 June 1994 (fl, fr), *Harris, D.J.* 5117 (E,WAG); Madibwé, close to St. Francois road 12 km NE of Bayanga., 2°58'N 16°18'E, 28 May 2001 (fl, fr), *Harris, D.J.* 7878 (E,WAG).

***Campylospermum excavatum* (Tiegh.) Farron**

Fig. 11

Bull. Jard. Bot. État Bruxelles 35: 396 (1965). – *Exomicrum excavatum* Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 340 (Dec. 1902). – Type: *Zenker 1077a* (holotype: P!; isotype: E(2x)!, G(2x)!, K!), Cameroon, Bipinde, 1896.

Ouratea mimfiensis Gilg., nom. nud.

Shrub or treelet up to 6 m tall, with branched stem; twigs with a whitish green coloured bark. *Stipules* persistent, triangular, **2–6(–10) mm long**. Leaf: petiole 3–5(–7) mm long;

leaf blade narrowly elliptic to narrowly elliptic-obovate, 9–17(–19) x 2–4(–5) cm, ratio 3–4(–6), base cuneate to narrowly cuneate, apex acute to acuminate, parchmentaceous, distinctly bullate between the lateral veins, upper side green, glossy, lower side paler green, margin serrulate, generally more distinctly so in the upper half, rarely almost entire; venation: midrib prominent above and below, main lateral veins 8–15(–19) on either side, 7–15 mm apart, prominent but sitting in a furrow above, prominent beneath, making a slight angle with the midrib and curved upward to run parallel to the margin, intermediate lateral veins 1 or 2 in between each pair of main laterals, prominent on both sides, tertiary venation scalariform, perpendicular to the midrib, very distinct on both sides or sometimes slightly distinct below. *Inflorescence* terminal, unbranched or sometimes branched, lax, its main axis (2–)4–10(–14) cm long, flattened to cylindrical; **pairwise scales at the base of peduncle absent**; bracts caducous, triangular, 1–3 mm long; racemes 0–2(–4), 2–4(–8) cm long; cymules 0.5–1.5 cm apart, 1–4(–6)-flowered. *Flower*: pedicel (4–)7–10 mm long, articulated at 1–3 mm from the base; sepals narrowly ovate, in flower 5–7 x 1.5–2 mm, in fruit 6–8 x 2–3 mm, base truncate, apex rounded; petals obovate, 6–7 x 3–4 mm, **cuneate at base, rounded at apex**; stamens: anthers 4–6 mm long; ovary c. 1–2 mm high; style 4–5 mm long, persistent in fruit. *Fruit*: receptacle c. 1 mm thick in flower, in fruit 4–6 thick and 5–6 mm in diameter; drupelets 1 to 2 well developed per receptacle, **broadly ellipsoid to broadly reniform**, 6–12 x 5–10 mm, immature ones reddish, mature ones black; cotyledons incumbent, dissimilar in size with a small outer cotyledon.

Notes: *C. excavatum* resembles *C. sulcatum* and *C. descoingsii*. For the distinction with the former, see Notes below that species. The latter has a longer main inflorescence axis, broader leaves and flowers sitting on shorter pedicels (see also the note under *C. vogelii*).

Distribution: Cameroon, southern Central African Republic, Equatorial Guinea, Gabon, and the Republic of the Congo (**Map 12**).

Ecology: in primary and secondary forest, high forest on mountain slope; at 20–440 m altitude.

Phenology: flowering from January to April and July, fruiting from February to May, also in September and November.

Uses: In case of chest problems, leaves are ground with seeds of *Afromomum melegueta*, pulverized and rubbed into scarifications (Neuwinger 2000).

IUCN conservation status: LC. EOO=389,139 km², AOO=101,075 km², locations=34, subpopulations=8 (cell width=28 km). This species has a considerable number of locations. Its recent collection is from 2011 and it occurs in protected areas such as the Dzanga-Sangha National Park (Central African Republic), the Monte Alen National Park (Equatorial Guinea) and the Minkébé National Park (Gabon). Therefore, the category of Least Concern seems most appropriate.

p.114

Tree up to 15 m tall, with branched trunk; twigs with brownish coloured bark. *Stipules* caducous, triangular, 4–5 mm long. *Leaf*: petiole 3–8 mm long; leaf blade **elliptic to narrowly elliptic or narrowly elliptic-obovate, (7-)13-26(-45) x (3-)5-8(-9) cm ratio 2-4**, base cuneate, apex from slightly acuminate to blunt, **coriaceous**, not bullate, upper side slightly glossy dark green, lower glossy medium green, **margin closely to distantly spinose-serrate**; venation: midrib flat to slightly prominent on the upper side, prominent on the lower side, main lateral veins generally 11–25 on either side, 5–25 mm apart, at a ± right angle with the midrib but curved upwards to run parallel to the margin, prominent on both sides, intermediate lateral veins 1–5 in between the main ones, prominent, **tertiary venation scalariform, sometimes joined by cross veinlets, perpendicular to the midrib, distinct on the upper side, very distinct on the lower side**. *Inflorescence* terminal, branched or occasionally unbranched, fairly dense, its main axis (7-)10–20(-31) cm long; **pairwise scales at the base of the peduncle absent**; racemes 0–5, (3-)6–18(-21) cm long, spread out ± horizontally, occasionally the lowest ones branched; **cymules 0.5–1 cm apart, (1-)3–10-flowered**. *Flower*: pedicel (5–)7–15(-17) mm, articulated at 1–4(-5) mm from the base; sepals narrowly ovate, **6–7 x 2–3 mm in flower, 6–7 x 3–5 mm in fruit**, apex acute, greenish-yellow in flower, red and patent in fruit; petals obovate, 5–10 x 4–8 mm, base cuneate, **apex rounded to slightly emarginate**; stamens: anthers 5–6 mm long; ovary c. 2 mm long; style c. 5 mm long. *Fruit*: receptacle c. 1 mm long in flower, 5 x 5 mm in fruit; drupelets 3 to 4 well developed per receptacle, ellipsoid to broadly ellipsoid, 6–10 x 4–6 mm; **cotyledons incumbent, dissimilar in size with a small outer cotyledon**.

Notes: This species is generally easily recognized by the leaves with spinulose-serrate margin, a branched inflorescence with comparatively small flowers in rather closely set cymules. Some forms are close to *C. bukobense*, but that species has papyraceous and more elongated leaves, and a less pronounced serrate leaf margin.

Specimens previously identified as *Ouratea laurentii* show some dissimilarities with typical *C. flavum*. Their inflorescence is either branched or not. When not branched, those specimens are close to *C. glaucum*, but differ by having a strongly dentate margin

and longer leaves.

The following specimens: *Preuss* 760, *Preuss* 829, *Lehmbach* 111 and *Deistel* 283 were cited as types of *C. monticola* in the protologue. The latter has been designated as lectotype of *C. monticola* since the other two specimens have not been traced. Lectotypes for *Ouratea laurentii* and *Ouratea spinuloso-serrata* were also designated. Both specimens have two duplicates present in BR and G respectively and the material has both flowers and fruits.

Distribution: from Guinea Bissau to Cameroon, the Central African Republic, Gabon, northern Republic of the Congo and the Democratic Republic of the Congo (**Map 13**).

Ecology: in primary and secondary forests, swampy, dry and riverine or gallery forest, and in coastal savannah; on sandy, laterite and clayish soil; at 15–2200 m altitude.

Phenology: flowering and fruiting observed all year round.

Vernacular names: **Cameroon:** Kpemtele (Bobili). **Democratic Republic of the Congo:** Bolili bo kikereke (turumbu). **Ghana:** Epebégai, Hiatso (Ta), Laba (Ewe). **Guinea Bissau:** N'Saunte (Nalu). **Nigeria:** Fulami (Yakaro), Yakaro/Nyambu (Fulfude).

IUCN conservation status: LC. EOO=5,492,550 km², AOO=6,062,220 km², locations=275 (cell width=502 km). This species is widely distributed from West to Central Africa. It is well represented in herbaria, with numerous recent collections, and so seems to be fairly common. Thus, the category of Least Concerned has been assigned.

Campylospermum gabonense Biss.

Blumea 58: 4 (2013; as '*C. gabonensis*'). – Type: *Breteler & Breteler-Klein Breteler* 13124 (holotype: WAG; isotype: LBV, WAG), Gabon, Moyen-Ogooué, ca. 20-30 km NNW of Ndjolé, 0°03'N, 10°45'E, October 2nd, 1994.

⇒ subsp. *gabonense*

Fig. 13

Tree or treelet, up to 7 m tall, with branched trunk; twigs with brownish bark. *Stipules* persistent, narrowly triangular, **7–15 mm long**. *Leaf*: petiole canaliculate above, 3–7 mm long; leaf blade narrowly elliptic to narrowly elliptic-obovate, **16–30(–35) x 6–10(–11) cm**, ratio 2–4.5, base cuneate to tapering, apex acuminate or sometimes acute, thick leathery to coriaceous, upper surface flat or rarely bullate, margin serrulate or sometimes entire toward the base, rarely entire, upper surface dark green, lower surface paler green, both sides glossy, young leaves purple-red; venation: midrib flattened above, prominent below, main lateral veins **14–27 on either side**, 6–23 mm apart, prominent on both sides, curved upward to run parallel to the margin, intermediate lateral veins 0 to 2 in between each pair of main laterals, not to slightly prominent on both sides, tertiary venation scalariform, **running perpendicular to the midrib**, indistinct on the upper side, slightly distinct on the lower. *Inflorescence* terminal, **unbranched**, erect, **compact**, its main axis 3–13 cm long; peduncle robust; pairwise scales persistent at the base of the peduncle, narrowly triangular; bracts persistent at the base of the cymules, triangular, 2–3 mm long; cymules 3–5(–10) mm apart, 4–8-flowered. *Flower*: pedicel

Map 14. Distribution of *Campylospermum gabonense* ssp. *australe* (○), *Campylospermum gabonense* ssp. *gabonense* (□) and *Campylospermum glaberrimum* (▲)

5–15 mm, **articulated at 3–9 mm from the base**; sepals ovate, in flower 7–9 x 2–3 mm, greenish, in fruit 9–10 by 3–4 mm, red; petals obovate, 10–15 x 5–9 mm, cuneate at base, rounded at apex, yellow; stamens: anthers 5–7 mm long; ovary c. 2 mm wide; style 6–7 mm long. *Fruit*: receptacle 3–4 mm wide; drupelets 1 to 2 well developed per receptacle, ellipsoid, c. 7 x 5 mm, black at maturity; cotyledons incumbent, dissimilar in size with a smaller outer cotyledon.

Notes: The species epithet was originally published as “gabonensis”, but the correct spelling is “gabonense”, an error here corrected.

Distribution: endemic to Gabon (Moyen-Ogooué and Ngounié provinces; **Map 14**).

Ecology: in primary and secondary forest, sometimes along rivers or streams; at 70–400 m altitude.

Phenology: flowers observed from August to November and in April; fruits collected from October to January.

IUCN conservation status: VU B2ab(ii,iii,iv). EOO=4,477 km², AOO=2,348 km², locations=13 (cell width=15.32 km). All known records of this taxon are from areas exposed to mining and/or logging activities rendering a decline in its AOO and/or quality of the habitat most likely and hence the ‘Vulnerable’ category has been assigned.

Key literature: Bissiengou et al. (2013).

⇒ subsp. **australe** Biss.

Blumea 58: 5 (2013; as ‘subsp. *australis*’). – Type: *Wieringa* 2852 (holotype: WAG!; isotype: BR!, LBV!, MO!), Gabon, Ogooué-Maritime, Rabi, 0.6 km on the road to platform Rabi 78, 1°55.1'S, 9°50.8'E, October 4th, 1994.

Like the typical subspecies, but the leaf blade bullate between the lateral veins or rarely flat and the scalariform tertiary veins running perpendicular to the main lateral veins.

Notes: The subspecies name was originally published as “*australis*”, but the correct spelling is “*australe*”, an error here corrected.

Distribution: endemic to Gabon (Ogooué-Maritime, western Ngounié and Nyanga provinces; **Map 14**).

Ecology: in primary, moist and wet forest, in valleys with small streams; on sandy soil; at 3–350 m altitude.

Phenology: flowers observed from October to December; fruits collected from October to January.

IUCN conservation status: VU B1/B2ab(ii,iii,iv). EOO=6,862 km², AOO=1,544 km², locations=15 (cell width=12.43 km). This taxon is known from only 15 recent collections, five of which fall within the Loango National Park and the Moukalaba-Doudou National Park. The remaining ten collections originate from logging and oil concessions while even the Loango park is under development threat from Chinese mining companies. Therefore, this subspecies is best placed in the Vulnerable category.

Monelasmum glaucum Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 332 (Dec. 1902). – Type: *Pobeguin 227* (holotype: P (2x)!), Ivory Coast, Grand-Lahon, December 1896.

Ouratea insculpta Gilg, Bot. Jahrb. Syst. 33(2): 263 (1904). – Type: *Rowlands n.s.* (holotype: B†; isotype: K!, P (2x)!), Upper Guinea: West of Lagos.

Tree up to 5 m tall, rarely lianescents, with multiple stems; twigs with pale or whitish bark. Stipules persistent, triangular, 2–4 mm long. Leaf: petiole 3–6 mm long, stout; leaf blade narrowly elliptic to elliptic or sometimes elliptic-obovate, (3-)5–16 x (1.5-)2–6 cm, ratio 2–3(-6.4), base cuneate to rounded, apex blunt to acute or occasionally acuminate but very apex always blunt to acute, coriaceous, margin almost entire to serrulate, upper side glossy, dark green, paler green beneath; venation: midrib flat to slightly prominent above, prominent below, main lateral veins 5–15 on either side, 5–15 mm apart, at a more or less right to slight angle with the midrib and curved upward to run parallel to the margin, not prominent on both sides, intermediate lateral veins 1–2 in between each pairs of main laterals, tertiary venation scalariform to the midrib, indistinct to slightly distinct on the upper side, indistinct to distinct on the lower. Inflorescence terminal or rarely axillary, unbrached or rarely with up to 4 racemes, lax, its main axis (1-)6–20(-31) cm long; peduncle woody at base, slender upward; racemes 0–2(-5), 3–5(-15) cm long; pairwise scales 1–2 mm long, persistent at the base of the peduncle; cymules 0.5–2 cm apart, 1–4-flowered, rarely 14-flowered. Flower: pedicel 7–18 mm long, articulated at c. 2–5 mm from the base; sepals elliptic, in flower 7–8 x 3 mm, pale green, in fruit 7–10 x 3–4 mm, erecto-patent and red, base rounded, apex obtuse; petals obovate, 8–14 x 7–9 mm, cuneate at base, rounded to slightly emarginate at apex; stamens: anthers 5–7 mm long; ovary c. 1 x 1 mm; style 6–7 cm long. Fruit: receptacle c. 1 x 1 mm in flower, c. 4 x 2 mm in fruit, red; drupelets 1 to 2 well developed per receptacle, ellipsoid to ovoid, c. 8 x 4 mm; cotyledons incumbent, dissimilar in size with a small outer cotyledon.

Notes: This species is morphologically similar to *C. congestum* but differs by its main lateral veins being not prominent on both sides and often longer pedicels (7–18 mm in *C. glaberrimum*, 4–11 mm in *C. congestum*).

Distribution: Guinea, Sierra Leone, Liberia, southern Mali, Burkina Faso, Ivory Coast, Ghana, Togo, Benin and Nigeria, with a single collection from Equatorial Guinea (**Map 14**).

Ecology: in secondary forest, along forest edges, in swampy, mangrove and riverine forest; on sandy, loamy, granitic and clayish soil; at 0–760 m altitude.

Phenology: flowers and fruits collected all year round.

Uses: The wood is reported to be usable, without indication of a purpose, and the plant (no specific part mentioned) to yield a dyestuff (Burkill, 1997).

Vernacular name: Benin: Alové; Nigeria: Otchireda (Igbuira).

IUCN conservation status: LC. EOO=2,397,370 km², AOO=2,359,270 km², locations=147 (cell width=276 km). This species is widely distributed in West Africa inside as well as outside National Parks, from the tropical to the dryer Sudanian savannah zone. It is frequently collected and well represented in herbaria, reasons why the category of Least Concern has been assigned.

Campylospermum glaucifolium Biss.

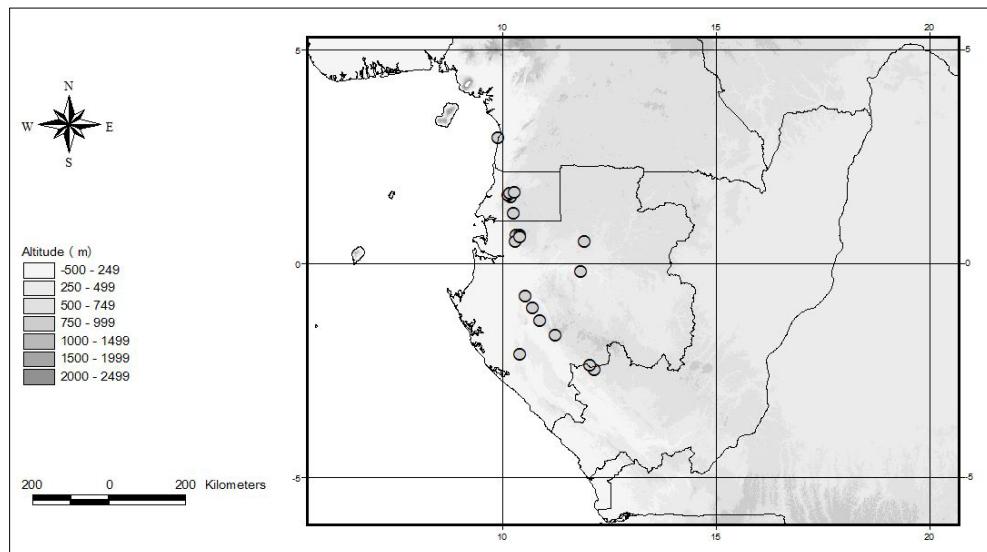

Blumea 58: 5 (2013). – Type: *J.J. de Wilde* et al. 10165 (holotype: WAG!; isotype: LBV!), Gabon, Estuaire, 1 km W of Nkan, along the road from Assok to Méla, 0°40'N, 10°19'E, January 23rd, 1991.

Treelet up to 2 m tall, with branched trunk; twigs with whitish bark. *Stipules* caducous, 2–3 mm long. **Leaf:** **petiole 7–15(–20) mm long**, canaliculate above; leaf blade narrowly elliptic to narrowly elliptic-obovate, **13–25(–30) x 4–7(–8) cm**, ratio **3.8–4.6**, base cuneate, apex acuminate, leathery to coriaceous, not bullate, margin serrulate, upper surface glossy, dark green but **turning glaucous when dry**, lower surface pale green, young leaves reddish; venation: midrib generally prominent on both sides, main lateral veins 14–16 on either side, 10–15 mm apart, slightly prominent above, prominent below, curved upward to run parallel to the margin, tertiary venation scalariform,

running perpendicular to the midrib thus causing the formation of a decreasing series of intermediate lateral veins, indistinct above, distinct below. **Inflorescence** terminal, **pendulous**, branched or unbranched, lax, its main axis (9–)15–33 cm long; peduncle slender; racemes 0–2(–3), 3–6(–10) cm long; pairwise scales persistent at the base of peduncle; bracts caducous, triangular, c. 2–3 mm long; cymules 0.5–1(–1.5) cm apart, 1–4-flowered. **Flower**: pedicel 3–12 mm, articulated at 1–3 mm from the base; sepals ovate, in flower 6–7 x 2–3 mm, green-yellowish, in fruit 8–9 x 3–4 mm, bright red; petals obovate, 7–9 x 4–5 mm, shortly clawed at base, rounded at apex; stamens: anthers 5–6 mm long; ovary c. 2 mm wide; style 6–7 mm long. **Fruit**: receptacle c. 3 mm wide, red; drupelets 1–4 well developed per receptacle, reniform 7–10 x 6–8 mm, black at maturity; cotyledons accumbent, similar in size.

Notes: This species resembles *C. calanthum* (Gilg) Farron, but differs by its glaucous upper leaf surface (at least when dry), longer petiole, and pendulous inflorescence that carries 0–2(–3) racemes.

Distribution: continental Equatorial Guinea (Rio Muni), Gabon and southwestern Republic of the Congo (Niari; see **Map 15**).

Map 15: Distribution of *Campylospermum glaucifolium*

Ecology: in primary and secondary forest, on creek banks and along swampy areas; at 50–1000 m altitude.

Phenology: flowers collected in January, April, July and August; fruits collected from March to May and in August.

IUCN conservation status: LC. EOO=72,683 km², AOO=23,157 km², locations=19 (cell width=65 km). This species, although being sub-endemic to Gabon, has a fairly wide

distribution and hence its EOO and AOO are comparatively large, and above the IUCN thresholds. Therefore, the category of 'Least Concern' seems most appropriate here.

***Campylospermum glaucum* (Tiegh.) Farron**

Fig. 15

Bull. Jard. Bot. État Bruxelles 35: 397 (1965). – *Exomicrum glaucum* Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 340 (Dec. 1902). – Type: *Zenker 1647* (holotype: P!; isotype: E!, G!, K(2x)!, P!, S!, WAG!, Z!), Cameroon, Bipinde, 1898.

Exomicrum membranaceum Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 340 (Dec. 1902). – Type: *Zenker 1030* (holotype: P!; isotype: E!, G!), Cameroon, Bipinde, 1898.

Monelasmum brachybotrys (Gilg) Tiegh., Ann. Sci. Nat., sér. 8, Bot. 18: 36 (June 1903). – *Ouratea brachybotrys* Gilg, Bot. Jahrb. Syst. 33: 270 (1904). – Lectotype (designated here): *Zenker 2180a* (holotype: K!; isotype: E!, G!, LY!), Cameroon, Bipinde.

Ouratea bella Gilg in Engl. & Prantl, Nat. Pflanzenfam. ed. 21: 73 (1925), nom. nud.

Treelet up to 8 m tall, with branched trunk; twigs with whitish bark. **Stipules** persistent, triangular, **3–4 mm long**. **Leaf:** petiole 5–7(–10) mm long; leaf blade **narrowly elliptic-obovate to narrowly elliptic**, **(7–)11–20(–23) x (2.5–)4–5(–7)** cm, ratio

2–3.8, base cuneate or sometimes rounded, apex acute to acuminate or sometimes tapering, papyraceous, not bullate, margin **serrulate to subentire, glaucous on the upper surface**; venation: midrib almost flat to prominent above, prominent beneath, main lateral veins (7-)10–18 on either side, **7–20(–25) mm apart, flat to slightly prominent on both sides**, at a ± right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins 2–3 in between each pair of main laterals, tertiary venation **scalariform, perpendicular to the midrib, distinct on both sides**. *Inflorescence* terminal, erect to erecto-patent, branched, dense, its main axis **(1–)2–4(–6) cm** long; pairwise scales few, persistent at the base of the peduncle; bracts persistent, **sometimes leaving a conspicuous scar**, triangular, 1–2 mm long; **racemes 1–3**, (1–)2–3 cm long; cymules **2–5 mm apart**, 1–6(–8)-flowered. *Flower*: pedicel **6–10(–12) mm long**, articulated at 2–4 mm from the base; sepals ovate, 5–7 x 1.5–3 mm in flower, 9–10 x 3–5 mm in fruit, greenish-yellow in flower, red in fruit; petals **obovate, 6–7 x 3–4 mm**, base cuneate to truncate, apex **emarginate**; stamens: anthers 3.5–6 mm long; ovary 1–2 mm long; style **persistent in fruit**, 4–5 mm long. *Fruit*: receptacle c. 1 mm thick in flower, 3 x 5 mm in fruit, red; drupelets 1 to 2 well developed per receptacle, **ellipsoid to slightly reniform**, 7–10 x 4–5 mm; cotyledons **incumbent, dissimilar in size with a small outer cotyledon**.

Notes: *C. glaucum* is characterized by its glaucous upper leaf surface. This is reminiscent of those sometimes encountered in *C. glaucifolium* which is, however, easily distinguished by its long, lax and pendant inflorescence.

The name *Ouratea brachybotrys* was published with several syntypes. Zenker 2180a has been designated as lectotype because it represents fruiting material and duplicates are distributed in 4 herbaria.

Distribution: Nigeria, Cameroon, southern Central African Republic, Equatorial Guinea, Gabon and Republic of the Congo (**Map 16**).

Ecology: in primary, secondary forest, understorey of open forest, swampy and periodically inundated forest, riparian forest and forest edges near rivers; at 40–1100 m altitude.

Phenology: flowering all year round; fruits observed in August, September, November and from January to May.

Vernacular name: Gabon: Avom.

IUCN conservation status: LC. EOO=364,900 km², AOO=188,880 km², locations=54 (cell width=87 km). This species is not under threat because most of its locations are found inside National Parks such as Moukalaba-Doudou, Loango, Lope, Ivindo and Minkebe, all in Gabon, Monte Alen in Equatorial Guinea, and Dzanga-Sangha in the Central African Republic. It is fairly frequently collected suggesting it is not rare. Therefore, the category of Least Concern has been assigned.

Ouratea gilgiana H.Winkl., Bot. Jahrb. Syst. 41: 282 (1908). – Type: Winkler 890 not

located. Neotype (designated here): *Versuchsanstalt Kamerun* 493 (holotype: B! isotype: FHO!), Cameroon, Botanischen Garten Victoria.

Treelite 6 m tall, with branched trunk; **branches upright**; twigs with pale brown-whitish bark. *Stipules persistent*, triangular, 1–2 mm long. *Leaf*: petiole 4–6 mm long; leaf blade **narrowly to very narrowly elliptic, (4–)6–10(–14) x (0.8–)1–2(–3) cm**, ratio 4–6, base cuneate, apex acute, **papyraceous to subcoriaceous**, not bullate, glossy on both sides, dark green above, paler green beneath, margin distantly and shallowly serrulate; venation: midrib strongly prominent on upper side, prominent on the lower; main lateral veins **4–7 on either side, 5–13 mm apart**, more prominent below than above, at a ± right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins **1–2** between each pair of main lateral ones, distinct on both sides, tertiary venation **scalariform**, indistinct on the upper side, distinct on lower side. *Inflorescence* terminal, **erect, branched, fairly dense**; its main axis (2–)4–9(–13) cm long; pairwise scales **persistent at the base of the peduncle, triangular**, small; racemes 2–3, ascendant, 3–6(–9) cm long; cymules 2–13 mm apart, **with 2–3 persistent, narrowly triangular bracts at their base**, 1–4-flowered. *Flower*: pedicel (8–)10–11(–13) mm long, articulated at 2–3(–4) mm from the base; sepals ovate, 8–9 x 3–4 mm in flower, 8–10 x 3–4 mm in fruit, greenish-yellow in flower, red in fruit; petals obovate, 11–13(–15) x 7–11 mm, base narrowly cuneate, apex **slightly emarginate**; stamens: anthers 4–8 mm long; ovary 1–2 mm long; style 5–6 mm long. *Fruit*: receptacle 1–2 mm thick in flower, in fruit 4–6 mm, reddish; drupelets 1 to 2 well developed per receptacle, **ellipsoid**, 6–4 x 3–4 mm; cotyledons incumbent, dissimilar in size with a small outer cotyledon.

Notes: The name *Ouratea dusenii* Engl. & Gilg, published in 1903, has been used most often in literature as the correct name for this species. Its type specimen *Dusen* 289 is probably lost in Berlin. However, the name *Monelasmum glomeratum* Tiegh (with type specimen *Thollon* 140) is also available for this species. It perfectly fits the description of the former, as well as its ecological environment. After studying the type, *Thollon* 140, it is clear the name refers to the same taxon. Since it was published in 1902, one year before *Ouratea dusenii*, *Monelasmum glomeratum* Tiegh. is the legitimate name to be used which necessitated the new combination *C. glomeratum* (Tiegh.) Biss.

The name *Ouratea gilgiana* was published with *Winkler* 890 as the type specimen. It could not be located and was probably destroyed during the World War II in Berlin. Therefore, a cultivated plant from the Victoria Botanical Garden (Cameroon) numbered 493 is designate here as neotype. The duplicates are in B and FHO and the material carries fruits.

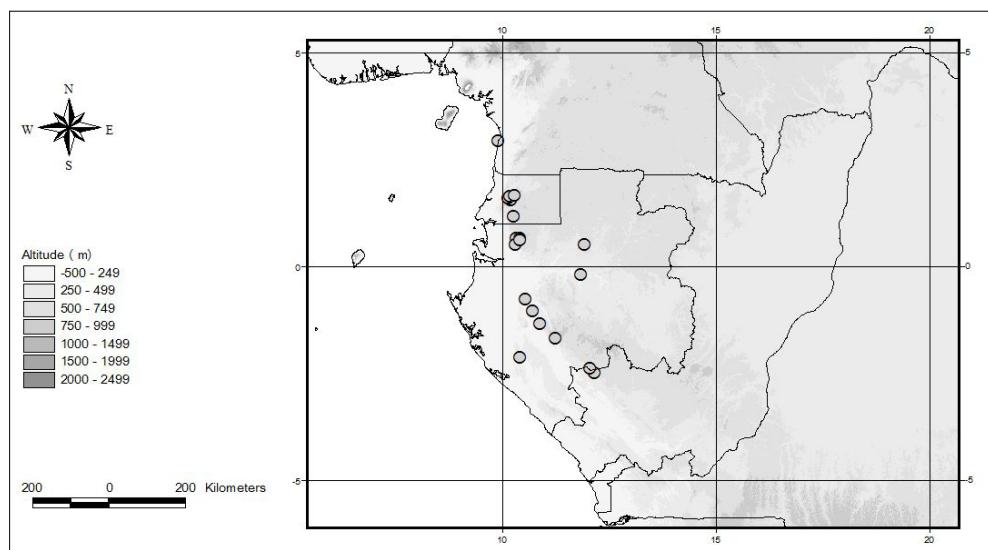

This species is close to *C. paucinervatum* by having relatively small, narrowly elliptic leaves. It differs, however, by having more bracts at the base of the cymules, its long and ascendant racemes and of course by having more lateral veins.

Distribution: Cameroon, Equatorial Guinea and Gabon (**Map 17**).

Ecology: in seasonally inundated gallery forest along rivers, on rocky river banks, in river beds; on rock white sandy soil; at 10-600 m altitude.

Phenology: flowering all year round; fruiting all year, except in September and November.

IUCN conservation status: LC. EOO=116,412 km², AOO=50,789 km², locations=27 (cell width=68 km). This species occurs mainly along rivers and in rocky river banks, habitats which are generally not suitable for human activities. Moreover, it is collected within National Parks such as Lopé in Gabon and Campo-Ma'an and Korup in Cameroon. It is fairly well represented in herbaria, suggesting it is not rare. Thus, the category of Least Concern seems most appropriate despite its rather limited area of distribution.

Key literature: Bissiengou & Sosef (2008), Hutchinson, Dalziel & Keay (1954), White & Abernethy (1997).

***Campylospermum klainei* (Tiegh.) Farron**

Bull. Jard. Bot. État Bruxelles 35: 398 (1965). – *Diphyllodium klainei* Tiegh., Bull. Mus. Hist. Nat. (Paris) 8: 376 (June 1902). – Type: *Klaine 157* (holotype: P!), Gabon, environs de Libreville, 1896.

Treelet up to 6 m tall, **monocaulous** bark whitish. **Stipules** caducous, triangular, up to 15 mm long. **Leaf:** petiole 0–5 mm long, **stout**; leaf blade **narrowly spatulate, (30–)44–70(–90) x 10–20 cm**, ratio **3.4–4.7**, **base cordate**, **apex acuminate**, **papery**, not bullate, margin serrulate in the distal half, indistinctly so in the basal half, upper side dull dark green, lower side glossy bright green; venation: midrib slightly prominent on the upper side, strongly prominent on the lower, **main lateral veins (22–)26–34 on either side, 7–30 mm apart**, prominent on the upper side, prominent to slightly prominent below, **making a slight angle with the midrib**, straight and only towards the margin slightly curved up, intermediate lateral veins 0–2 in between each pair of main laterals, tertiary venation scalariform, **running perpendicular to the main lateral veins**, joined by cross veinlet, **distinct on both sides**. **Inflorescence** terminal on a **3–4 cm long lateral twig (and thus appearing to be axillary)**, unbranched, dense, its main axis 15–20 cm long; peduncle angular to slightly flattened, **bearing two subopposite, slightly reduced leaves or small leafy bracts at its base**, leafy bracts ovate and 3–4 x 1–1.5 cm; pairwise scales absent; cymules **2–5 mm apart, 4–10-flowered**. **Flower:** pedicel 10–15 mm long, articulated at 2–3 mm from the base; sepals ovate, in flower

7–9 x 4–5 mm, apex obtuse, green, in fruit 16–18 x 5–6 mm, red, coriaceous, curved over the drupelets; petals **ovovate**, 13–15 x 4–5 mm, **base shortly clawed, apex rounded**; stamens: anthers 5–6 mm long; ovary 1–2 mm high; style 5–6 mm long. *Fruit*: receptacle flat, enlarged to 4–5 mm wide; drupelets 1 to 2 well developed per receptacle, **ellipsoid**, **10–11 x 5–7 mm**; **cotyledons incumbent, similar in size**.

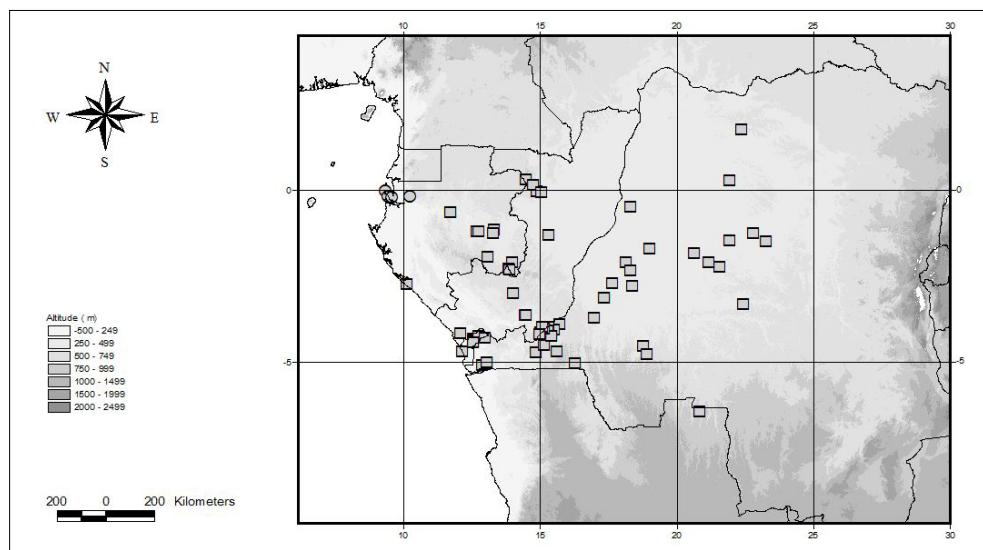

Notes: This species resembles *C. mannii* (Oliv.) Tiegh. morphologically. It differs by having papery leaves and inflorescences that are born on a short lateral twig. Furthermore, their distributions do not overlap; while *C. mannii* occurs in Cameroon and south-eastern Nigeria, *C. klainei* is a narrow endemic from north-western Gabon.

Distribution: only known from north-western Gabon, from the Crystal Mountains (Kingué) to the Mondah area (**Map 18**).

Ecology: in primary forest on hill slopes, on rocky or iron-rich soil; at up to 80 m altitude.

Phenology: flowering in August and September.

IUCN conservation status: CE B1/B2(ii,iv). EOO=1,072 km², AOO=436 km², locations=4 (cell width=10 km). This species occurs within the Mondah Forest Reserve in Gabon, but being close to the capital, this reserve and the zone around it is becoming very fragmented by human activities leading to a decline of suitable habitat for this species. Therefore, the category of Critically Endangered has been assigned.

Campylospermum laeve* (De Wild. & T.Durand) Farron*Fig. 16**

Bull. Jard. Bot. État Bruxelles 35: 399 (1965). – *Ouratea laevis* De Wild. & T.Durand, Bull. Soc. Roy. Bot. Belgique 38(2): 34 (1899). – *Monelasmum laeve* (De Wild. & T.Durand) Tiegh., Ann. Sc. Nat., sér. 8, Bot. 16: 327 (1902). – Type: *Cabra* 58 (holotype: BR!; isotype: BR!), Democratic Republic of the Congo, Tshela, 1897.

Monelasmum lecomtei Tiegh., Ann. Sc. Nat., sér. 8, Bot. 16: 331 (Dec. 1902). – Type: *Lecomte* s.n. (holotype: P!; isotype: P!), Congo, forêt de Moabi, sur le sentier de Brazzaville, January 1894.

Ouratea buchneri Gilg, Bot. Jahrb. Syst. 33: 270 (1904). – *Monelasmum buchneri* (Gilg) Tiegh., Ann. Sc. Nat. sér. 8, Bot. 18: 36 (1903). – Type: *Buchner* 541 (B, probably destroyed). Neotype (designate here). *Missão de Estudos Florestais a Angola* 684 (holotype: LISC!), Angola, Cabinda, Maiombe, Buco Zau, June 14th, 1960.

Ouratea lundensis Cavaco, Bull. Mus. Natl. Hist. Nat. sér. 2, 26: 641 (1954). – *Ouratea* sp., Conspl. Fl. Angolensis: 297 (1951). – Type: *Gossweiler* 13570 (holotype: COI!; isotype: B!, BM!, K! US!), Angola, Nordeste da Lunda, Dundo, 10th, September 1946. **syn. nov.**

Tree up to 15 m tall, with branched stem; bole up to 16 cm in diameter; twigs with whitish-brownish bark. *Stipules* caducous, triangular to narrowly triangular, 6–9 mm long. *Leaf*: petiole **(6–)10–20(–25) mm long, stout**; *leaf blade* elliptic to narrowly elliptic or narrowly elliptic-oblong (6–)14–29(–36) x (2.5–)4–8(–10) cm, ratio (2.0–)2.5–6.0(–8.5), base attenuate to narrowly cuneate or occasionally broadly cuneate, apex acuminate, often abruptly so, or rarely blunt, coriaceous, slightly glossy above, **margin distinctly thickened and often revolute**, finely and regularly serrulate; venation: midrib flattened to slightly prominent on the upper side, prominent beneath, main lateral veins **9–12(–15) on either side, 10–30(–42) mm apart**, mostly prominent above, prominent to slightly so beneath, at a ± right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins 1–7 in between each pair of main laterals, less distinct above, prominent below, tertiary venation **scalariform, joined by cross veinlets**, perpendicular to the midrib, less distinct above, distinct beneath. *Inflorescence* terminal, branched, lax, its main axis (5–)15–30(–35) cm long, **more or less angular**; pairwise scales absent; racemes 1–5(–7), (2–)5–9(–14) cm long, **erecto-patent to horizontal**, sometimes branched again; cymules 0.5–1.5 cm apart, 1–7-flowered; bracts caducous, 1–2 mm long. *Flower*: pedicel **10–12 mm long**, articulated at 1–2 mm from the base; sepals ovate, (6–)9–11 x 3–5 mm in flower, 8–12 x 4–6 mm in fruit, apex rounded or sometimes acute, greenish-yellow in flower, red in fruit; petals obovate, 6–12 x 3–5 mm, base cuneate, **apex rounded**; stamens: anthers 4–6 mm long; ovary 1–2 mm long; style 5–6 mm long. *Fruit*: receptacle enlarged to c. 5 x 5 mm in fruit; drupelets 3 to 4 well developed per receptacle, **ellipsoid**, 9 x 5–6 mm; cotyledons incumbent dissimilar in size with a small outer cotyledon.

Notes: The type specimen of the name *Ouratea buchneri* was *Buchner* 541. It could not

be located, and was probably destroyed at B. Therefore, a neotype is designated here. It originates from the same area (Angola). Unfortunately, collections of *Ouratea buchneri* from Angola do not have duplicates. We selected *Missão de Estudos Florestais a Angola* 684 because it carries both flowers and fruits.

This species is easily distinguished by its revolute, finely and regularly serrulate margin. The range in leaf ratio is remarkable: from 2.0 to 8.5. It resembles *C. engama* with which it shares the long petiole, but differs by having a leaf blade that is not decurrent onto the petiole, and by its shorter racemes. It is pictured on a 1986 postal stamp from Gabon.

Distribution: Gabon, Republic of the Congo, Democratic Republic of the Congo and Angola (Cabinda, Lunda Norte province) (**Map 18**).

Ecology: in high and gallery forest; at 30–750 m altitude.

Phenology: flowering and fruiting all year round.

Use: The wood is used as timber whereas the leaves could be used against headache or toothache. Dried leaves are smoked like tobacco (Bamps and Farron 1967).

Vernacular names: **Angola:** Libambo, Limbembe (Kikongo). **Democratic Republic of the Congo:** Elonaanai, Itelisho, Lyonga (Mongo); Ifanjanjoku (Bokuma); Ntumbo (Bokoro); Mumpele, Mumpeve (Luki), Lulaki lu mbwa.

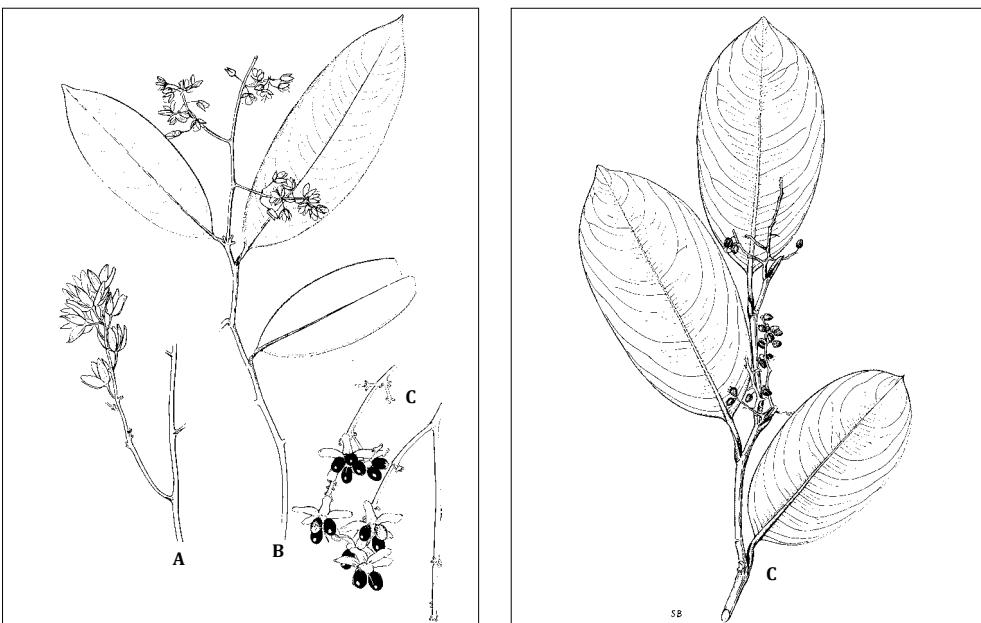

Figure 16. *Campylospermum laeve*. A. Fruiting branch with persistent sepals. B. Flowering branch. C. Fruiting branch. Drawings by Sabine Bousani

IUCN conservation status: LC. EOO=1,114,450 km², AOO=650,281 km², locations=62 (cell width=150 km). This species is widely distributed in both the Democratic Republic of the Congo and the Republic of the Congo, where it does not appear to be rare. Recent collections are from Gabon and collected in Lopé National Park. Thus, the category of Least Concern seems most appropriate.

Monelasmum setigerum Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 334 (Dec. 1902). – Type: *Zenker s.n.* (holotype: Pl; isotype: COI!), Cameroon, Yaoundé, 1896.

Ouratea macrobotrys Gilg, Bot. Jahrb. Syst. 33: 268 (1904). – Lectotype (designated here): *Zenker & Staudt 768* (holotype: B†; isotype: BM!, COI!, GOET, K!, LE, P, Z), Cameroon, Yaunde, 1894-95.

Ouratea ituriensis Gilg & Mildbr., Wiss. Erg. deut. Zentr.-Afr. Exped., Bot. 2: 558 (1913). – Type: *Mildbraed* 2984 specimen not located. Neotype (designated here): *Lebrun* 2752 (holotype: BR!; isotype: K!, WAG!), Democratic Republic of the Congo, Buta, Titule, May 1931.

Ouratea flamignii De Wild., Rev. Zool. Afr. 7, Suppl. Bot.: B50 (1920). – Type: *Flamigni* 116 (holotype: BR!; isotype: BR!), Democratic Republic of the Congo, Bena-Dibele, June 19th, 1905.

Ouratea bracteato-pedunculata De Wild., Ann. Soc. Sci. Bruxelles, sér. B 48, compt. rend.: 26 (1928). – Type: *Claessens* 268 (holotype: BR!; isotype: BR!), Democratic Republic of the Congo, Bena-Dibele, June 12th, 1909.

Ouratea dubiosa De Wild., Ann. Soc. Sci. Bruxelles, sér. B 48, compt. rend.: 28 (1928). – Type: *Claessens* 396 (holotype: BR!; isotype: BR!), Democratic Republic of the Congo, Katako Kombe, January 1910.

Tree or treelet up to 10 m tall, with branched stem; **bole up to 10 cm in diameter**; twigs with whitish-brownish bark. **Stipules persistent**, narrowly triangular, (3-)4-10 mm long. **Leaf**: petiole 2-7 mm long; leaf blade narrowly elliptic-obovate to narrowly elliptic or rarely elliptic-obovate or elliptic, **(5-)13-23(-32) x (1.5-)6-9(-11) cm**, ratio **2-4.5**, base narrowly cuneate to rounded, apex gradually acuminate, papyraceous to subcoriaceous, slightly bullate or sometimes smooth, in dry condition **set with tiny bumps in between the tertiary veins on the upper surface giving it a ‘rough’ appearance**, glossy above, margin serrulate; venation: midrib prominent above and below, main lateral veins 7-18 on either side, **10-15(-20) mm apart**, prominent but often running in a slight depression above, prominent below, at a ± right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins **1-2 in between each pair of main laterals**, distinct, tertiary venation **scalariform**, perpendicular to the midrib, with numerous cross-veins giving it a reticulate appearance, **distinct on both sides**. *Inflorescence* terminal, branched, lax, its main axis (5-)11-35(-50) cm long; pairwise scales **persistent at the base of the peduncle**, triangular, 5-10 mm; racemes (1-)2-8, (4-)7-21(-23) cm long; cymules 1-2 cm apart, 1-12-flowered. *Flower*: pedicel (7-)10-18(-20) mm long, articulated at 1-5(-7) mm from the base; sepals ovate, 5-7 x 2-3 mm in flower, 5-8 x 2.5-4 mm in fruit; petals **obovate**, 7-12 x 5-10 mm, base attenuate, **apex emarginate**; stamens: anthers 4-6 mm long; ovary c. 1 x 1 mm; style 3-5 mm long. *Fruit*: receptacle enlarged up to c. 6 x 5 mm in fruit; drupelets 1 to 3 well developed per receptacle, **ellipsoid**, 4-10 x 4-6 mm; cotyledons incumbent, dissimilar in size with a small outer cotyledon.

Notes: *Monelasmum sulcatum* and *Ouratea macrobotrys* were simultaneously described based on duplicates of the same collections. A lectotype *Zenker & Staudt* 768 is designated for both species. It has several duplicates located in seven herbaria and the fruits are present in all herbarium sheets.

The type specimen (*Mildbraed 2984*) of the name *Ouratea ituriensis* could not be located. Therefore, another specimen *Lebrun 2752* has been appointed as neotype. It has fruits and the duplicates are kept in 4 different herbaria. It was collected more or less in the same area.

This species shares some features with *C. reticulatum*, especially the tertiary venation with many cross veinlets is reminiscent of that species. However, the tiny bumps on the often slightly bullate upper leaf surface generally makes *C. laxiflorum* stand out (see also the note under *C. reticulatum*). In addition it has persistent stipules, whereas *C. reticulatum* has caducous ones.

Distribution: from south-western Senegal to Ghana and from southern Nigeria to the Democratic Republic of the Congo and northern Angola (Malanje) (**Map 19**).

Ecology: primary and secondary forest, high forest on slopes, in swampy, inundated forest, in forest along rivers or streams and gallery forest; on sandy soil; at 0–1500 m altitude.

Phenology: flowering and fruiting all year round.

Vernacular names: Democratic Republic of the Congo: Engbongbo (Babua), Bolilibi Kikereke, Yeka Olili Ikekeleke (Turumbu), Lofandjandjoku (Lokundu), Luhaha (Kitembo).

IUCN conservation status: LC. EOO=4,784,680 km², AOO=6,481,380 km², locations=322 (cell width=531 km). This species is common and widely distributed in Central Africa, less so in West Africa. It has numerous recent collections and thus the category of Least Concern has been assessed.

Specimens examined:

ANGOLA, Cabinda: Reserva Indigena do Chiaco, Maiombe. 4°53'S 12°34'E. Alt: 25m, 1 November 1951 (fl), *Câmeira 151* (LUA); **Lunda Norte:** Cassádil, nos valles de rio Cuillo. 8°00'S 19°40'E, (fl), *Marques, S.A. 201* (COI).

***Campylospermum lecomtei* (Tiegh.) Farron**

Fig. 18

Bull. Jard. Bot. État Bruxelles 35: 399 (1965). – *Ouratea lecomtei* Tiegh., Bull. Mus. Natl. Hist. Nat. 8: 51 (Jan. 1902). – *Bisetaria lecomtei* (Tiegh.) Tiegh., J. Bot. (Morot): 45 (Febr. 1902). – Type: *Lecomte s.n.* (holotype: Pl; isotype: P(2x!)), Congo, bords du Kouilou entre Kitabi et Kakamoeka, 1893.

Bisetaria febrifuga (Engl & Gilg) Tiegh., Ann. Sc. Nat., sér. 8, Bot. 18: 14 (June 1903). – *Ouratea febrifuga* Engl & Gilg, Bot. Jahrb. Syst. 33: 257 (1904). Type: *Laurent s.n.* (holotype: BR!), Bas Congo, August 1893.

Shrub or treelet up to 2 m tall, with branched stem; twigs upright, often grouped at the end of the branches or stem, with whitish bark. Stipules persistent, linear, 5–13 x 1 mm. Leaf: petiole 1–2 mm long, swollen; leaf blade very narrowly elliptic to linear, (5–)7–11(–13) x (0.5–)1–1.5 cm, ratio (3–)7–13, base narrowly cuneate, apex tapering into a bristle-like acumen, coriaceous, not bullate, upper side green, slightly glossy, lower side paler green, dull, margin thickened, distantly serrulate; venation: midrib prominent above and below, main lateral veins numerous, c. 1 mm apart, straight, more prominent above than below, more or less at a right angle with the midrib, intermediate lateral veins absent, tertiary venation indistinct on both sides. Inflorescence terminal, pendulous, usually unbranched, lax, its main axis (5–)9–20 cm long; pairwise scales at the base of peduncle persistent; bracts persistent, linear, 3–6 mm long; cymules 5–20 mm apart, 1–5-flowered. Flower: pedicel (5–)7–10(–13) mm long, articulated at 1–4 mm from the base; sepals oblong to narrowly elliptic, in flower 6–9 x (1–)2–3 mm, in fruit 6–12 x 3–4 mm, base rounded, apex obtuse; petals obovate, 6–10 x 3–6 mm, cuneate at base, rounded to slightly emarginate at apex; stamens: anthers 4–6(–8) mm long; ovary 1–2 mm long; style 4–5 cm long. Fruit: receptacle c. 1 mm thick in flower, in fruit 2–3 mm; drupelets 1–3 well developed per receptacle, ovoid, 7–9 x 4–5 mm; cotyledons accumbent, similar in size.

Notes: This species is easily recognized by its very narrow leaves. In that sense it resembles *C. glomeratum* and *C. louisii*, but can be easily distinguished by its numerous parallel main lateral veins and long and linear stipules.

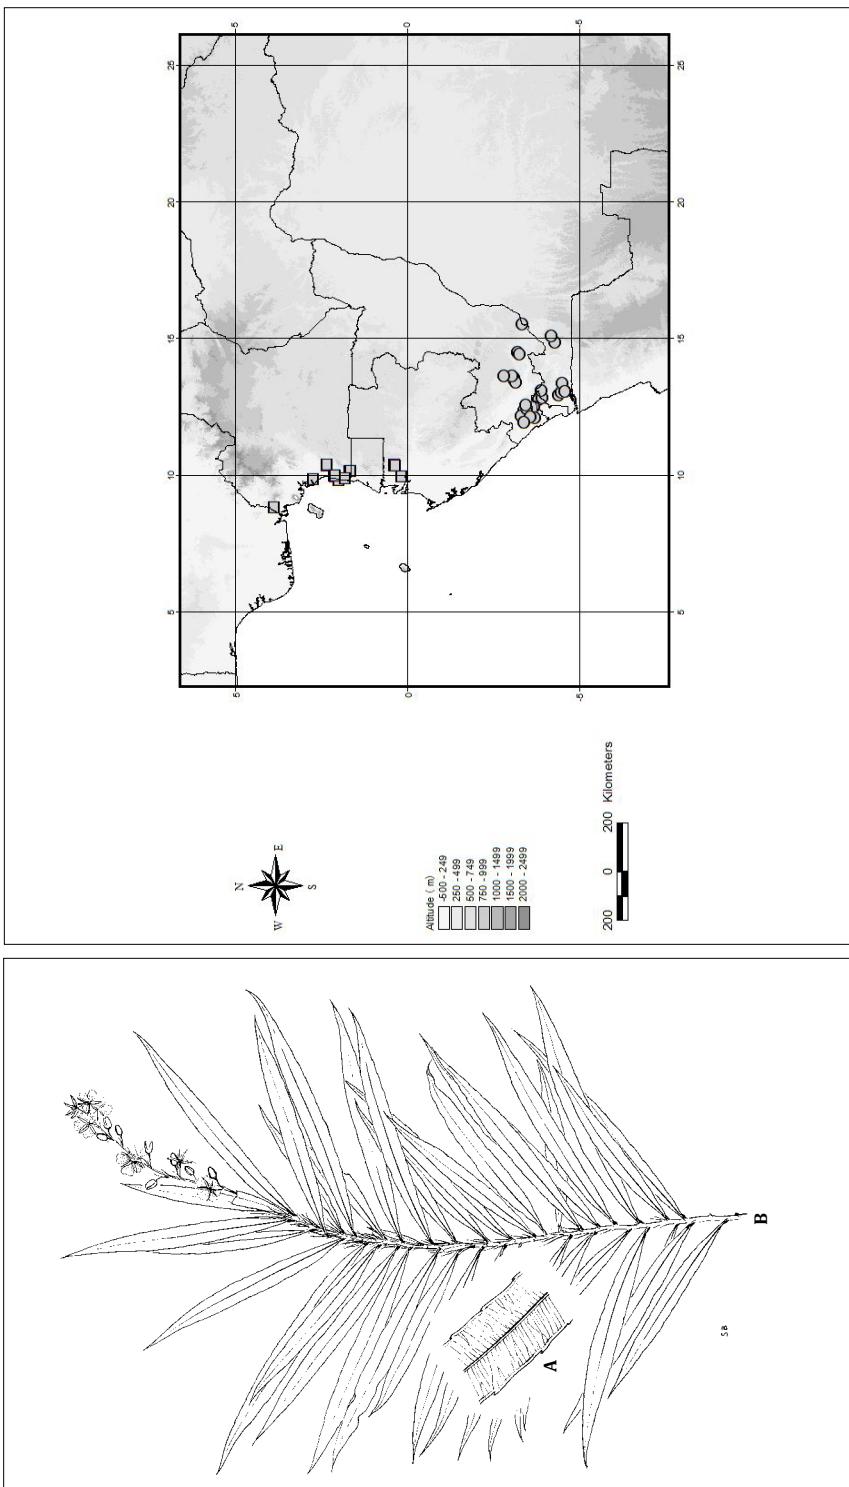

Figure 18. *Campylospermum lecomtei*. A. Flowering branch. Drawings by Sabine Bousani
Map 20. Distribution of *Campylospermum lecomtei* (○) and *Campylospermum longestipulatum* (□)

Distribution: southern Republic of the Congo, south-western Democratic Republic of the Congo (Bas-Congo) and Angola (Cabinda) (**Map 20**).

Ecology: understory of primary and secondary forest; on granitic or dry soil; no exact altitudinal data known, but probably at 100–600 m.

Phenology: flowering and fruiting observed in January to April, June, August, November and December.

Vernacular names: Democratic Republic of the Congo: Ditsasa ya gumba (Mayumbe).

IUCN conservation status: NT B1/B2(ii,iii). EOO=64,085 km², AOO=25,575 km², locations=27 (cell width=40 km). Although *C. lecomtei* has a fairly small distribution range, it does not appear to be rare, since a fair amount of specimens (42) have been collected. Still, the most recent collection dates from 1992. Moreover, the species occurs mainly outside protected areas in regions where logging activities are common, which is why the category of Near Threatened has been assigned.

Specimens examined:

Type: Zenker 3577 (holotype: BR!; isotype: E!, G!, S!, US!), Cameroon, Bipinde, 1908.

Ouratea cella Gilg ex De Wild., Pl. Bequaert. 4: 492 (1929), nom. nud.

Treelet up to 3 m tall, with branched stem; twigs with whitish bark. *Stipules* persistent, **narrowly triangular, 14–17 mm long**. *Leaf*: petiole 3–10 mm long, fairly slender to stout, generally canaliculate above; leaf blade narrowly **elliptic or narrowly elliptic-ovovate oblong-elliptic, (10–)12–22(–30) x (3.5–)4–6(–9) cm**, ratio 2–3.5, base cuneate, decurrent onto the petiole, apex acute to acuminate, **parchmentaceous, bullate**, margin serrulate in the distal half, generally entire in the basal, upper side glossy, dark green, glossy, paler green beneath; venation: midrib strongly prominent on both sides, **main lateral veins (10–)15–20(–23) on either side, 7–20 mm apart**, ± at a right angle with midrib but curved upward to run parallel to the margin, **sunken on upper side, prominent on lower side**, intermediate lateral veins 0–1 in between each pair of main laterals, **flattened beneath, shallowly impressed above**, tertiary venation scalariform, perpendicular to the midrib, **indistinct on both sides**. *Inflorescence* terminal, **unbranched, dense, its main axis 2–4 cm long**; peduncle robust; pairwise scales triangular, persistent at the base of the peduncle; cymules only **1–2 mm apart**, with 1 or 2 broadly triangular bracts at their base. *Flower*: pedicel 11–13(–20) mm long, articulated at 3–5 mm from the base; sepals ovate, in flower 6–8 x 3–4 mm, in fruit 12–13 x 3–5 mm, base rounded, apex obtuse; petals obovate, 9–12 x 7–9 mm, cuneate at base, rounded at apex; stamens: anthers 4–5 mm long; ovary c. 1 x 1 mm, style 5–6 mm long. *Fruit*: receptacle c. 1 x 1 mm in flower, c. 4 x 2 mm in fruit; drupelets 1 to 2 well developed per receptacle, **reniform**, c. 8 x 4–6 mm; cotyledons **incumbent, dissimilar in size with a small outer cotyledon**.

Notes: This species is morphologically similar to *C. sulcatum*, because of its bullate leaves and unbranched, compact inflorescence. It can be distinguished from the latter by its long and persistent stipules, its generally more numerous main lateral veins and its indistinct tertiary venation. De Wildeman (1929) highlights the fact that some specimens of *C. longestipulatum* were first distributed from the herbarium of Berlin under the name *Ouratea cella* Gilg, a manuscript name present only on herbarium labels and never formally published. He did not use that name because some specimens of *O. cella* were confused with those of *C. oliverianum* (see note under *C. sulcatum*). Quite some material placed here under *C. longestipulatum* was previously identified as *C. oliverianum* by Farron. However, the type specimen of that name clearly belongs to *C. sulcatum*.

Distribution: coastal regions of Cameroon and northern Gabon (**Map 20**).

Ecology: in primary and secondary forest, high forest, littoral forest, forest along streams; at 50–530 m altitude.

Phenology: flowers collected in January, March, June and August; fruits collected from February to April and in October and December.

IUCN conservation status: NT B1/B2(iii,iv). EOO=38,627 km², AOO=22,448 km², locations=17 (cell width=53 km). Although its recent collection is from 2010 and some of its locations occur in protected areas such as the Crystal Mountains National Park in Gabon and the Mount Elephant and Edea Reserves in Cameroon, it has a fairly small distribution area and is only known from 21 collections from 17 localities. Therefore, the category of Near Threatened seems most appropriate.

Specimens examined:

CAMEROON, Littoral: Edea Reserve, near Lake Tissongo. 3°35'N 9°54'E, January 1978 (fl), Thomas, D.W. 298 (C,K,WAG); **South Province:** Kribi, piste menant au Mont éléphant, 7 km après village Bidou III. 2°48.23'N 10°02.04'E. Key literature: Bissiengou et al. (2013).

***Campylospermum louisii* Bissiengou & Sosef**

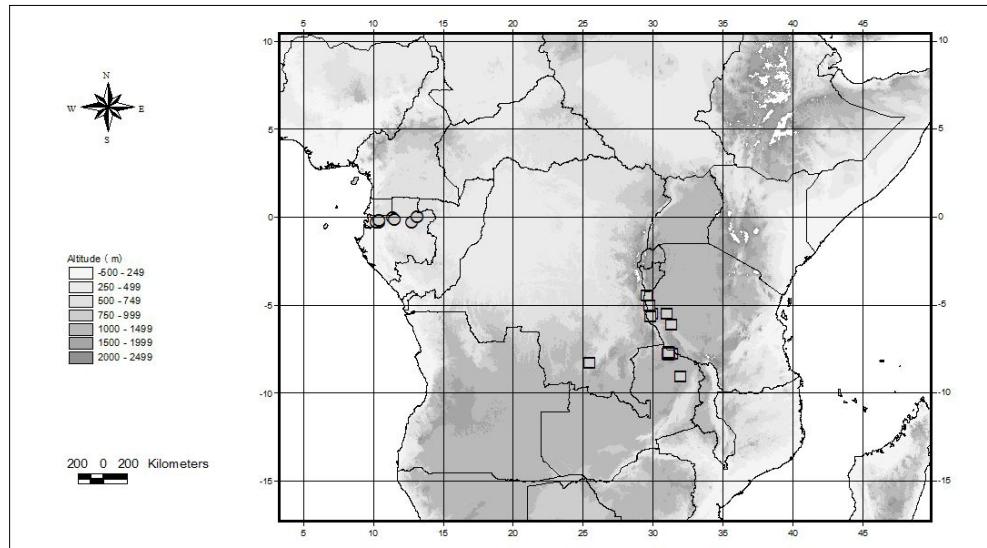

Blumea 53: 627 (2008). – Type: A.M. Louis 2849 (holotype: WAG!; isotype: LBV!, MO!), Gabon, Estuaire Province, route Tchimbélé vers Kingué à 19.6 Km, February 23rd, 1988.

Treelet up to 1.5 m high, with branched stem; twigs with whitish bark. Stipules: persistent, narrowly triangular, c. 3 mm long. *Leaf:* petiole 1.5–5 mm long; leaf blade **narrowly to very narrowly elliptic**, **9.5–28 x 1.3–2.4 cm**, ratio **4.5–15**, base cuneate to attenuate, apex long tapering and sometimes mucronulate at the very tip, papyraceous, not or slightly bullate, margin entire to serrulate with distant, reduced teeth, upper surface glossy dark green, lower surface greenish; venation: midrib **prominent but running**

through a gully on the upper surface, prominent on the lower, main lateral veins (**12–15–20 on either side, 5–12 mm apart**, more or less at right angles with midrib but strongly curved up toward the margin, prominent on both surfaces, intermediate lateral veins absent, tertiary venation scalariform towards the margin but reticulate towards the midrib, scalariform venation perpendicular to the midrib, distinct on both sides. *Inflorescence* terminal, branched, slender, lax, its main axis (4–)7–18 cm long; racemes 1–4, 2–6 cm long; pairwise scales **persistent at the base of the peduncle**, minute; cymules 1–2.5 cm apart, 1–3(–4)-flowered; bracts caducous, narrowly triangular, 1–2 mm long. *Flower*: pedicel 3–10 mm long, articulating at 1–5 mm from the base; sepals narrowly ovate, 5–6 x 2–3 in flower, 3–8 x 1–3 mm in fruit, apex rounded; petals not observed; stamens not observed; ovary c. 0.5 mm high; style 3 mm long. *Fruit*: receptacle accrescent to a ± globose shape; drupelets only 2 to 3 well developed per receptacle, ellipsoid, 5–9 x 4–7 mm, green turning pink (presumably immature) and finally black; cotyledons incumbent, more or less equal.

Notes: The similarity to and distinction from *C. laeve* was already discussed in Bissiengou & Sosef (2008).

Distribution: endemic to Gabon (Map 21).

Map 21. Distribution of *Campylospermum louisi* (○) and *Campylospermum lunzuense* (□)

Ecology: in primary and secondary forest; at 500–650m altitude.

Phenology: flowering in February; fruiting in March, May and November.

Vernacular name: Gabon: Alen-opwbon (Fang).

IUCN conservation status: VU. EOO=9,912 km², AOO=7,509 km², locations=10 (cell width=33 km). This species occurs at higher altitudes in the Crystal Mountains and the

Bélinga Mountains in Gabon where logging activities are rare, although there is some threat for habitat destruction by mining activities. The Vulnerable category is assigned based on the fact that it has a limited distribution and is only known from 10 localities.

Specimens examined:

Key literature: Bissiengou & Sosef (2008).

***Campylospermum lunzuense* (N.Robson) Biss.**

Fig. 19

Campylospermum lunzuensis (N.Robson) Biss., Blumea 58: 7 (2013). – *Ouratea lunzuense* N.Robson, Bol. Soc. Brot., ser. 2, 36: 38 (1962). – *Gomphia lunzuense* (N.Robson) Verdc., Fl. trop. E. Africa, Ochnac.: 47 (2005). – Type: *Bullock 3877* (holotype: K!), Zambia, Lunzua River, 19 miles west of Abercorn, 1951.

Treelite up to 6 m tall, with branched stem; twigs spreading, wiry, with whitish bark. *Stipules* caducous, triangular, 2–3 mm long. *Leaf*: petiole 2–5 mm long; leaf blade elliptic to narrowly elliptic, **(4-)7-13(-19) x (1.5-)2-3.5(-4.5) cm**, ratio **3.5-6.5**, base attenuate, apex **slightly acuminate or sometimes acute**, mucronate, coriaceous to parchmentaceous, not bullate, upper side slightly glossy, dark green, lower side medium green, **margin spinose-serrate, entire towards the base**; venation: midrib prominent on both sides, main lateral veins 3–12 on either side, 15–30(–70) mm apart, at a ± right angle with the midrib but strongly curved upwards to run parallel to the margin, intermediate lateral veins 0–1 in between each pair of main laterals, distinct on both sides, **tertiary venation scalariform along the margin and perpendicular to the midrib but reticulate towards the midrib**, very distinct on both sides. *Inflorescence* terminal, unbranched or branched, dense to lax, its main axis 1–8 cm long, **slender**; pairwise scales caducous; racemes 0–3, 1–6 cm long; cymules 1–5 mm apart, 2–6-flowered; bracts persistent, triangular, 1–1.5 mm long. *Flower*: pedicel **9-22(-30) mm long, articulated at (2-)3-7(-12) mm from the base**; sepals narrowly ovate, 6–7 x 2–3 mm in flower, 7–8 x 2–4 mm in fruit, apex obtuse to rounded; petals obovate, 6–9 x 3–4 mm, base cuneate, apex rounded; stamens: anthers 4–6 mm long; ovary c. 1 mm high; style 4–5 mm long. *Fruit*: receptacle c. 1 mm long in flower, 4 x 4 mm in fruit; drupelets 2 to 3 well developed per receptacle, **cylindric-ellipsoid**, 7–8 x 5–5.5 mm; cotyledons incumbent, ± similar in size.

Notes: *C. lunzuense* was synonymized with *C. reticulatum* by Farron (1965) without justification. However, it differs from *C. reticulatum* by having a spinulose-serrate leaf margin, pedicels that articulate generally much higher up, often a denser inflorescence and its cotyledons being similar in size. Therefore, we agree with Verdcourt (2005) in recognizing *C. lunzuense* as a distinct species. *C. lunzuense* is also similar to *C. warneckei* from which it differs by having a spinulose-serrate leaf margin and pedicels articulated well above the base.

Distribution: western Tanzania, northern Zambia, with one collection in south-eastern Democratic Republic of the Congo (**Map 21**).

Ecology: in riverine forest, sometimes on steep river banks, in dry gallery forest and evergreen rain forest; at 900–1524 m altitude.

Phenology: flowers observed in May, June and from August to October; fruits observed in May, June and from August to November.

IUCN conservation status: LC. EOO=252,064 km², AOO=52,312 km², locations=15 (cell width=72 km). This species is not frequently collected (only 21 specimens known) and hence seems to be fairly rare. It has not been collected since 1993. However, the area of occupancy is fairly large as is the number of locations. Some specimens come from National Parks such as the Gombe National Park in Tanzania, Lunzua in Zambia and some from a Forest Reserve near the Mbala Hills. Therefore, the category Least Concern seems most suitable.

Specimens examined:

Key literature: Exell et al. (1963), Robson (1963), Verdcourt (2005).

***Campylospermum lutambense* (Sleumer) Biss.**

Campylospermum lutambensis (Sleumer) Biss, Blumea 58: 7 (2013). – *Ouratea lutambense* Sleumer, Repert. Spec. Nov. Regni Veg. 39: 278 (1936). – *Gomphia lutambense* (Sleumer) Verdc. Fl. trop. E. Africa, Ochnac.: 52 (2005). – Type: *Schlieben* 6110. (holotype: B†; isotype: BR!, G!, Z!), Tanzania, 50 km W. Lindi, Lake Lutamba, Noto Plateau, March 9th, 1935.

Tree up to 4 m tall, rarely scandent, with branched stem; twigs with brownish bark. **Stipules persistent**, triangular, 3–5 mm long. **Leaf**: petiole 0–5 mm long, stout; leaf blade elliptic to narrowly elliptic or elliptic-obovate, **10–22(–30) x 3–6(–8.5) cm**, ratio **2.25–3.2**, **base rounded, apex blunt to rounded**, coriaceous, not bullate, margin entire to distantly serrulate, upper side very glossy, dark green, lower side glossy bright green; venation: midrib flattened above, prominent below, main lateral veins **14–30(–35)** on either side, **4–9 mm apart**, making a slight angle with the midrib and curved upwards, **prominent on both sides**, intermediate lateral veins 0–2 in between each pair of main laterals, prominent on both sides, **tertiary venation reticulate, very distinct on both sides**. **Inflorescence** terminal, unbranched or sometimes with 1 or 2 short racemes, **robust**, its main axis (4–)6–9(–13) cm long; racemes **0–2**, c. **1–1.5 cm long**; pairwise scales caducous; cymules **1–5 mm apart, 1–6-flowered**; bracts persistent, triangular, 1–1.5 mm long. **Flower**: pedicel 5–10 mm long, articulated at 1 mm from the base; sepals **ovate**, in flower 6 x 3–4 mm, in fruit 7 x 3–4; petals oblong-spathulate, **9–10 x 5 mm**, truncate at base, **rounded** at apex; stamens: anthers 5–6 mm long; ovary c. 1 mm long; style c. 5 mm long. **Fruit**: receptacle 6 mm thick; drupelets 1 to 2 well developed per receptacle, **reniform**, 7 x 5 mm; cotyledons **accumbent, similar in size**.

Notes: This species was previously only known from south-eastern Tanzania, but recently a single specimen from south-eastern Democratic Republic of the Congo (Katanga prov.) was discovered. It is similar to *C. densiflorum* by having thick and coriaceous, blunt leaves, but the prominent main lateral veins and especially the striking reticulate tertiary venation readily sets it apart.

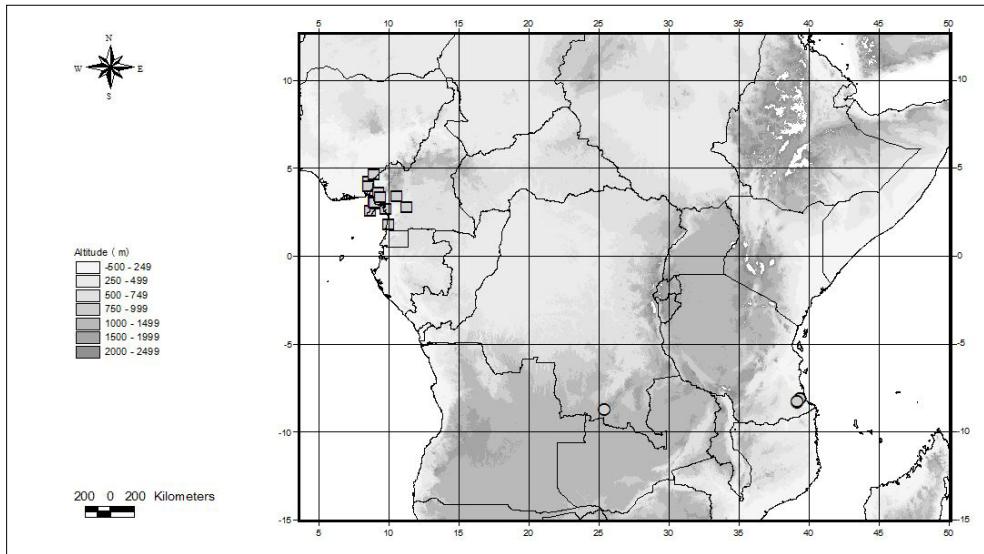

Distribution: Democratic Republic of the Congo (Katanga prov.) and Tanzania (Lindi prov.) (**Map 22**).

Ecology: in semi-evergreen forest; on grey sandy soil; at 700–1430 m altitude.

Phenology: flowers observed in March and December; fruits in February and March.

IUCN conservation status: CE B1/B2(i,ii), EOO=18,870 km², AOO=46,972 km²,

locations=4, subpopulations=2 (cell width=153 km). This species is only known from four collections, and thus seems to be very rare. Its most recent collection is from 2004. Three collections are found in the Rondo Forest Reserve (Tanzania). Although the AOO suggests a category of Least Concern, this species could be in threat since one of its only two subpopulations is found outside a protected area. Furthermore, collections found in Rondo were last collected in 1991 and its presence needs confirmation. Therefore, for now, the category of Vulnerable seems most appropriate.

p.166

green, lower side glossy bright green; midrib prominent above and below, **main lateral veins 20–26 on either side**, 12–30 mm apart, prominent but running through a gully above, slightly prominent below, **making a slight angle with the midrib** and slightly curved up towards the margin, intermediate lateral veins 0–1(–2) in between each pair of main laterals, tertiary venation scalariform, running perpendicular to the main lateral veins, joined by cross veinlet, distinct on both sides. **Inflorescence axillary, unbranched, dense**; its main axis 8–25(–32) cm long, angular to slightly flattened; pairwise scales at the base of the peduncle absent; cymules **0.3–1.5(–2.5) cm apart, 9–28-flowered**. **Flower**: pedicel 8–15 mm long, articulated at 2–4 mm from the base; sepals elliptic to elliptic-ovate, in flower 8–9 x 4–5 mm, green, in fruit 12–15 x 7–10 mm, red, coriaceous, apex obtuse, incurved over the drupelets; petals obovate, 11–15 x 6 mm, base truncate, apex rounded; stamens: anthers 6–7 mm long; ovary 2 mm high; style c. 6 mm long. **Fruit**: receptacle flat, enlarged in fruit to 8–9 mm in diameter; drupelets 1 to 3 well developed per receptacle, **ovoid to ellipsoid, 8–12 x 6–7 mm; cotyledons incumbent, of similar size**.

Notes: This species is morphologically similar to *C. klainei* (Tiegh.) Farron from Gabon. It can be distinguished by its axillary inflorescence whereas it is terminal in *C. klainei*. Moreover, *C. klainei* has reduced leaves or leafy bracts at the base of its inflorescence whereas, *C. mannii* does not. The distribution of the two species does not overlap.

Distribution: south-eastern Nigeria (Calabar), Cameroon (West and Southwest province), and Equatorial Guinea (Bioco) (**Map 22**).

Ecology: in primary or secondary high forest, on hill slopes; on iron-rich soil, young volcanic soil or sometimes rocky places; at 100–200 m altitude.

Phenology: flowering in February, March and December; fruits observed in February, March, August and December.

IUCN conservation status: NT B1/B2(iii, iv). EOO=66,854 km², AOO=18,717 km², locations=14 (cell width=41 km). This species has not been collected in the past 10 years and is known from only 15 specimens suggesting it is rare. It occurs in highly disturbed forest and some of its specimens were collected in what today are protected areas, like Pico de Basilé on the island of Bioco, South Bakundu in Cameroon and Oban in Nigeria. Thus, the category of Near Threatened seems most appropriate.

***Campylospermum nutans* (Hiern) Biss.**

Blumea 58: 7 (2013). – *Ouratea reticulata* (P.Beauv.) Engl. ex Gilg var. *nutans* Hiern, Cat. afr. pl. 1: 123 (1896). – *Monelasmum nutans* (Hiern) Tiegh., Ann. Sci. Nat., Bot. 16, sér. 8: 328 (Dec. 1902). – *Ouratea nutans* (Hiern) Exell, J. Bot. 65, Suppl. 1: 59 (1927). – Type: *Welwitsch 4606* (holotype: BM!; isotype: K!), Sao Tomé and Principe, Insulae Principes, Pico de Papagais, September 1853.

Monelasmum henriquesii Tiegh., Ann. Sc. Nat., ser. 8, Bot. 16: 335 (Dec. 1902). Type: *Henriques 36* (holotype: COI!), Sao Tomé, August 1903. **syn. nov.**

Treelet, up to 4 m tall, with branched stem; twigs with whitish bark. *Stipules* caduous, triangular. *Leaf*: petiole 3–5 mm long, sometimes canaliculate; leaf blade narrowly elliptic, **8–19 x 2–5 cm**, ratio **3.5–5**, base cuneate, apex acuminate, **papyraceous**, not bullate, upper surface slightly glossy dark green, lower surface dull green, margin regularly serrulate; venation: midrib **prominent above, slightly prominent below**, main lateral veins **12–15 on either side, 6–16 mm apart**, prominent on both sides, at a ± right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins 0–1 in between each pair of main laterals, tertiary venation **scalariform**, perpendicular to the midrib, **very distinct on both sides**. *Inflorescence* terminal or rarely axillary, branched, lax, its main axis 15–20 cm long; pairwise scales at the base of the peduncle absent; bracts absent; racemes 1–3, 5–14 cm long, **lax and wiry**; cymules 0.5–2 cm apart, 1–8-flowered. *Flower*: pedicel **15–20 mm long**, **articulated at (4–)6–10 mm** from the base; sepals narrowly ovate, 5–8 x 2 mm in flower, in fruit 6–8 x 3–4 mm, apex acute; petals obovate, 6–10 x 4–6 mm, base cuneate, apex rounded to slightly emarginate; stamens: anthers 3.5–5 mm long; ovary c. 1 mm

high; style 4–8 mm long. *Fruit*: receptacle 2–4 mm wide; drupelets 1–2 well developed per receptacle, ellipsoid or ellipsoid-ovate to globose, 7–10 x 5–8 mm; cotyledons incumbent, dissimilar in size with a small outer cotyledon.

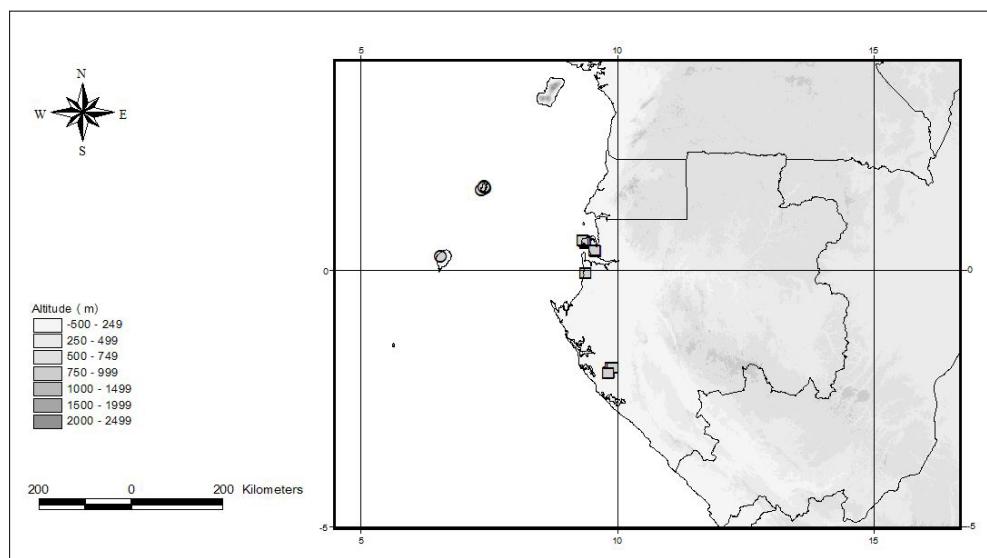

Notes: This species is known from only 11 specimens. Although it is close to *C. reticulatum*, and has originally been described as a variety of that species, I agree with Exell (1927, 1944) that it is sufficiently distinct to be regarded as a separate species. It differs from *C. reticulatum* by having a scalariform tertiary venation, papyraceous leaves and a pedicel articulating further up. Finally, true *C. reticulatum* seems to be absent from São Tomé and Príncipe, adding a geographical distinction to the whole.

Distribution: endemic to São Tomé and Príncipe (**Map 23**).

Ecology: in primary and secondary forest; at 150–670 m altitude.

Phenology: flowering in February, March, May, September and December; fruits observed in February, May, September and December.

IUCN conservation status: EN B1/B2(i,ii). EOO=386 km², AOO=1,266 km², locations=8 (cell width=18 km). This species is only known from 11 collections and its most recent collection is from 1999. Occurring on only two small islands (Príncipe and São Tomé), its area of occurrence and occupancy are very small, but it does seem to be present in protected areas such as Zona Ecologica in Príncipe. Therefore, the category of Endangered seems most suitable.

Map 23. Distribution of *Campylospermum nutans* (○) and *Campylospermum occidentale* (□)

Key literature: Exell (1927, 1944).

***Campylospermum occidentale* Biss.**

Campylospermum occidentalis Biss., Blumea 58: 6 (2013). – Type: *Haegens & v.d. Burgt 106* (holotype: WAG!; isotype: LBV), Gabon, Ogooué-Maritime, Rabi-Kounga, road to Divangui, 1°54'S, 9°55'E, December 6th, 1993.

Treelite up to 4 m tall, with branched stem; twigs with brownish bark. *Stipules* caducous, triangular, 2–3 mm long. *Leaf*: petiole 2–5 mm long; leaf blade narrowly elliptic to narrowly elliptic-obovate, **6–16 x 1.5–4.5 cm**, ratio **3–4**, base cuneate, apex slightly acuminate, **papery**, not bullate, margin entire to serrulate, glossy dark green above, paler green below; venation: midrib slightly prominent above, prominent below, main lateral veins 7–11 on either side, 9–20 mm apart, curved upward to run parallel to the margin, prominent on both sides, intermediate lateral veins 0(–1) but the scalariform tertiary venation producing a series of weaker veins connecting to the midrib, tertiary venation scalariform, perpendicular to the midrib, very distinct on both sides. *Inflorescence* terminal, branched, lax, its main axis slender, 4–8(–12) cm long; racemes 1–4(–6), 1–7(–11) cm long, held ± horizontally, **not seldom with secondary or even tertiary branches rendering the inflorescence a corymbose shape**; pairwise scales at the base of peduncle absent; bracts early caducous; cymules (5–)10–15 mm apart, 1–2(–3)-flowered. *Flower*: pedicel 4–10(–15) mm, articulated at 1–6 mm from the base; sepals ovate, in flower 5–7 x 2–3 mm, greenish-yellow, in fruit 6–7 by 3–3.5 mm, red, apex blunt; petals obovate, 5–11 x 4–7 mm, cuneate at base, rounded to emarginate at apex; stamens: anthers 3–4 mm long; ovary c. 2 mm wide; style c. 4 mm long. *Fruit*: receptacle c. 3 mm wide, red; drupelets 1–3 well developed per receptacle, ellipsoid, 8 x 5–6 mm, orange to orange-red at maturity; cotyledons incumbent, similar in size.

Notes: *C. occidentale* is close to *C. nutans*, but it differs by having fewer lateral veins and by having branched racemes that give the inflorescence a corymbose appearance.

The only sheet available with fruiting material seems to present mature drupelets, and the label says these (as well as the sepals) are orange, instead of the normal black condition. Future observations need to confirm this aberrant feature.

Distribution: endemic to Gabon, only found in the coastal plain, in the Ogooué-Maritime (Rabi-Kounga) and Estuaire (Mondah forest and Bikele) provinces (**Map 23**).

Ecology: primary and secondary, moist forest, near swampy areas; on sandy soil; at 5–30 m altitude.

Phenology: flowers collected from August to November; fruits observed from November to December.

IUCN conservation status: VU B1ab(ii, iii, iv). EOO = 5959 km², AOO = 3388 km², locations = 4 (cell width = 29.10 km). This species seems to have a disjunct distribution, but this is uncertain because the area between the two occupied areas is not well explored. In a situation involving a disjunct distribution the sliding scale grid size method leads to an overly large estimation of especially the AOO. Some of the occurrences in the vicinity of the capital Libreville are under threat of habitat destruction due to urbanization and overexploitation. This is likely to lead to a decline in the area of occupancy and/or number of populations or even extent of suitable habitat and hence we propose the category Vulnerable.

ambacensis Hutch. & Dalz., Fl. W. trop. Afr., ed. 1, 1: 192–193 (1927), nom. nov. – Type: *Mann* 12 (holotype: K!), Nigeria, Ambas bay, February 1861.

Campylospermum letouzeyi Farron, Adansonia n.s. 9: 117 (1969). – Type: *Letouzey* 1595 (holotype: Pl!; isotype: NEU!, SRFK!, YA!), Cameroon, forêt du Mélong près Bouda, March 1953. **syn. nov.**

Treelite, up to 8 m tall, with branched stem; twigs with whitish-brownish bark. *Stipules* persistent, triangular, 4–6 mm long. *Leaf*: petiole 0–11 mm long, stout; leaf blade narrowly elliptic-obovate, 16–31(–41) x 4–10(–13) cm, ratio **3–4.4**, base **rounded to cordate**, apex acute to slightly acuminate, papyraceous to coriaceous, not bullate, margin serrulate in the distal ¼, upper side slightly glossy dark green, lower side glossy medium green; venation: midrib **flattened, slightly prominent to sunken above**, prominent below, main lateral veins **30–50 on either side, 5–25 mm apart**, not prominent above, prominent below, making a slight angle with the midrib and curved upwards to run parallel to the margin, intermediate lateral veins 0–1 in between each pair of main laterals, distinct, tertiary venation **scalariform**, perpendicular to the main lateral veins, distinct on both sides. *Inflorescence* terminal or rarely axillary, **when axillary composed of a woody peduncle carrying 2 subopposite leafy bracts or reduced leaves at the apex from which a raceme emerges, unbranched or rarely with 1–2 racemes, dense**, its main axis (7–)11–27(–40) cm long, slender, generally naked in its lower third; racemes **0(–2), 14–15 cm long**; pairwise scales **persistent at the base of peduncle**, triangular, 3–4 mm long; cymules 1–10 mm apart, 2–10-flowered, **typically elongated when mature** (up to 10 mm long), sometimes supported by a bract of up to 6 mm. *Flower*: pedicel 6–12 mm long, **supported by c. 3 imbricate tiny bracts**, articulated at 1–2 mm from the base; sepals elliptic to oblong, in flower 4–6 x 2–3 mm, in fruit 7 x 2 mm, apex obtuse; petals broadly obovate, 6–10 x 5–8 mm, base **truncate**, apex **emarginate**; stamens: anthers 2–4 mm long; ovary c. 1 x 1 mm; style c. 3 mm long. *Fruit*: receptacle c. 1 mm thick in flower, 3 x 3 mm in fruit; drupelets 1 to 3 well developed per receptacle, ellipsoid to broadly ellipsoid, 7–8 x 5–6 mm; **cotyledons incumbent, similar in size**.

Notes: *C. zenkeri* and *C. letouzeyi* are here regarded as synonyms of *C. oliveri*. *C. oliveri* was previously only known from the type specimen collection which was collected during a stage where the inflorescence was old enough to evolve into a new twig thus carrying some leaves. This feature was the only morphological character that distinguished *C. oliveri* from *C. zenkeri* and *C. letouzeyi*. The phenomenon was also studied in the field (in *C. elongatum* and former *C. zenkeri* and *C. letouzeyi*), where it could be observed that in over-mature plants the old and formerly pendulous inflorescence axis curves up to form a leafy twig. The terminal growth of the primary branch being continued by an axillary bud. This phenomenon is apparently rare, but does not indicate any taxonomic distinction but rather a developmental stage.

C. oliveri resembles *C. elongatum* because of the large leaves with a rounded to cordate

base and unbranched inflorescence. However, *C. oliveri* is a branched shrub or treelet (not monocaulous) with not all leaves crowded apically, has a cylindrical peduncle (flattened in *C. elongatum*), pedicels articulating at 1–2 mm from the base and characteristic shortly elongated cymules with numerous bracts supporting the flowers.

Distribution: south-eastern Nigeria and Cameroon (South and South-west provinces) (**Map 24**).

Ecology: in primary and secondary forest, on forested slopes, in riverine rain forest; on marshy, sandy and clayish soils; at 20–1000 m altitude.

Phenology: flowering from January to June and from October to December; fruits observed in March, April and June.

IUCN conservation status: NT B1/B2(iii,iv). EOO=58,611 km², AOO=37,722 km², locations=39 (cell width=42 km). This species is fairly often collected, especially in comparison to its rather small area of distribution and so appears not to be rare. However, it occurs mainly outside of any protected area. Therefore, it is reasonable to apply the category of Near Threatened.

Specimens examined:

CAMEROON, Central Province: c. 40 km SSW. of Eséka, S. of Badjob. 3°32'N 10°34'E. ***Campylospermum paucinervatum* Sosef**

Blumea 52: 15 (2007). – Type: *Harris* 8338 (holotype: WAG!; isotype: E!, K!, LBV!, MO!), Gabon, Ogooué-Maritime Province, Loango National Park, Nick's camp, by Louri lagoon, c. 12 km south of Iguela, May 3rd, 2005.

Shrub or treelet up to 2 m tall, with branched stem; twigs with whitish bark. **Stipules** caducous, narrowly triangular, **3–5 mm long**. **Leaf**: petiole 0–2 mm long; leaf blade **narrowly elliptic or sometimes very narrowly elliptic, 3–9.5(–13) x 0.7–2(–3) cm**, ratio **2.5–8**, base **attenuate**, apex acute to slightly acuminate, **the very top apiculate, coriaceous**, not bullate, upper side glossy, dark green, lower side slightly paler, green, margin entire in the lower half to lower third, distal part distantly serrulate; venation: midrib slightly prominent on both sides, main lateral veins **0–2(–5) on either side, 10–35 mm apart**, prominent on both sides, **branching off in the lower part of the leaf and strongly curved upwards to form a prominent marginal vein which runs just inside the margin of the blade**, intermediate lateral veins absent, tertiary venation scalariform, perpendicular to the midrib, forming a series of numerous veins connecting to the midrib, **distinct on both sides**. **Inflorescence** terminal, branched, lax, its main axis **2–5(–10) cm long**; racemes 1–3, **up to 3 cm long, ending with persistent bracts at the tip**; pairwise scales at the base of the peduncle absent or few; **bracts persistent at the base of each cymule**, triangular, **up to 1.5 mm long**; cymules **3–5 mm apart**, **1–2-flowered**. **Flowers**: pedicel 7–12 mm long, articulated at 1–3 mm from the base; sepals elliptic-ovate, c. 5 x 2 mm in flower, 7 x 3 mm in fruit, rounded at apex, cuneate at base; petals **broadly spatulate, 6–8 x 3.5–5 mm**, base attenuate, apex rounded; stamens: anthers c. 4 mm long; ovary 1–2 mm long; style c. 4 mm long. **Fruit**: receptacle

± globose, c. 1 mm wide in flower, enlarged to 3–5 mm wide in fruit; drupelets 1–2 well-developed per receptacle, ± **reniform**, 5–6 mm in diameter; **cotyledons** incumbent, **dissimilar in size with a small external cotyledon**.

Notes: After publication of this species in 2007, additional specimens from the Republic of the Congo and north-western Angola (Cabinda) have been located. In addition to what Sosef et al. (2007) wrote about affinities with other *Campylospermum* species (notably *C. glomeratum*), it is also similar to *C. plicatum*, which has similar racemes carrying persistent bracts at the top.

Distribution: Gabon, Republic of the Congo and north-western Angola (Cabinda) (**Map 24**).

Ecology: in forest, forest-savanna edges, coastal thicket; on white sand; at 10–40 m altitude.

Phenology: flowers observed in May and November; fruits observed in May, June and August.

IUCN conservation status: VU B1/B2(ii,iii). EOO=12,084 km², AOO=9,064 km², locations=7 (cell width=48 km). This is a recently described and rare species with a restricted distribution and habitat. Its oldest record is from 1959 (Angola); its most recent one from 2012. It is known from only 7 herbarium specimens, 3 of which originate from within Loango National Park in Gabon. It is a coastal species and thus subject to habitat loss due to human activities. Therefore, the category of Vulnerable has been assigned.

Specimens examined:

– Type: *Griffon du Bellay* 296 (holotype: P!), Gabon, Pyrat, October 1863.

Monelasmum strictum Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 330 (Dec. 1902). – *Campylospermum strictum* (Tiegh.) Farron, Bull. Jard. Bot. État Bruxelles 35: 402 (1965).

– Type: *Guiral s.n.* (holotype: P!), Equatorial Guinea, exploration du Benito, 1885. **syn. nov.**

Monelasmum engleri Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 335 (Dec. 1902). – Type: *Welwitsch s.n.* (holotype: COI!), Angola. **syn. nov.**

Exomicrum kouiloui Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 339 (Dec. 1902). – Type: *Lecomte B.110* (holotype: P!), Democratic Republic of the Congo, bords du Kouilou, January 3rd, 1894. **syn. nov.**

Exomicrum pseudospicatum (Gilg) Tiegh., Ann. Sci. Nat., sér. 8, Bot. 18: 38 (June 1903). – *Ouratea pseudospicata* Gilg, Bot. Jahrb. Syst. 33: 263 (1904). – Type: *Vanderyst s.n.* (holotype: BR!), Democratic Republic of the Congo, Moanda, 1891. **syn. nov.**

Ouratea gymnoura Gilg & Mildbr., Wiss. Erg. deut. Zentr.-Afr. Exped., Bot. 6: 559 (1913). – Type: *Zenker 4682* (holotype: P!; isotype: BR!, MO!, P!, S!), Cameroon, Bipinde, 1913.

Ouratea goossensii De Wild., Pl. Bequaert. 4: 476 (1929). – Type: *Goossens 1657* (holotype: BR!; isotype: BR!), Democratic Republic of the Congo, Yambuya, May 1921.

Tree up to 5 m tall, with branched stem; twigs with pale brown bark. *Stipules* caducous, triangular, 3–4(–6) mm long. *Leaf*: petiole 3–6(–10) mm long; leaf blade narrowly elliptic to elliptic or narrowly elliptic-obovate **(7–)9–18(–22) x (2–)3–6(–7) cm**, ratio **2.5–4**, base cuneate or sometimes obtuse, **apex slightly to distinctly acuminate and then with a 8–15 mm long acumen, papyraceous to parchmentaceous**, not bullate, dark green above, paler green below, glossy on both sides, margin almost smooth to very shallowly serrulate, the teeth with a black tip; venation: midrib slightly prominent on both sides, main lateral veins **(5–)7–11** on either side, **7–26 mm apart**, prominent on both sides, more or less at a right angle with the midrib but **strongly curved upward** to run parallel to the margin for a long stretch, intermediate lateral veins **0–3 between each pair of main laterals**, prominent on both sides, tertiary venation **scalariform, joined with cross veinlet**, reticulate towards the midrib, distinct above, very distinct below. *Inflorescence* terminal, branched, lax, its main axis **(7–)19–30(–41) cm long**; pairwise scales at the base of peduncle caducous, triangular; racemes **(1–)4–10, erecto-patent, (3–)6–17(–22) cm long, terminating in few persistent bracts**; cymules 0.5–1 cm apart, 1–7-flowered, **each cymule with a persistent, sometimes leafy, triangular, 2–6(–8) mm long bract at its base**. *Flower*: pedicel **(6–)8–13(–15) mm long**, articulated at 2–5 mm from the base; sepals narrowly ovate to ovate, in flower 5–7 x 2–3 mm, in fruit 7–10 x 3–5 mm, base truncate, apex rounded; petals obovate, 7–9 x 4–6 mm, **cuneate** at base, **rounded** at apex; stamens: anthers 4–5 mm long; ovary c. 1–2 mm long; style 5–6 mm long. *Fruit*: receptacle enlarged in fruit up to 4–5 mm; drupelets 2 to 3 well developed per receptacle, **ellipsoid-oblong**, 8–14 x 5–6 mm; cotyledons incumbent, dissimilar in size, with a small outer cotyledon.

Notes: *C. plicatum* is readily distinguished by its leaves with a long acumen. It shares the presence of persistent bracts at the tip of each raceme with *C. paucinervatum*. *Ouratea pseudospicata* was considered to be a synonym of *C. reticulatum* by Farron (1965), who gave no reason for his choice. After having studied the type specimen, we conclude that

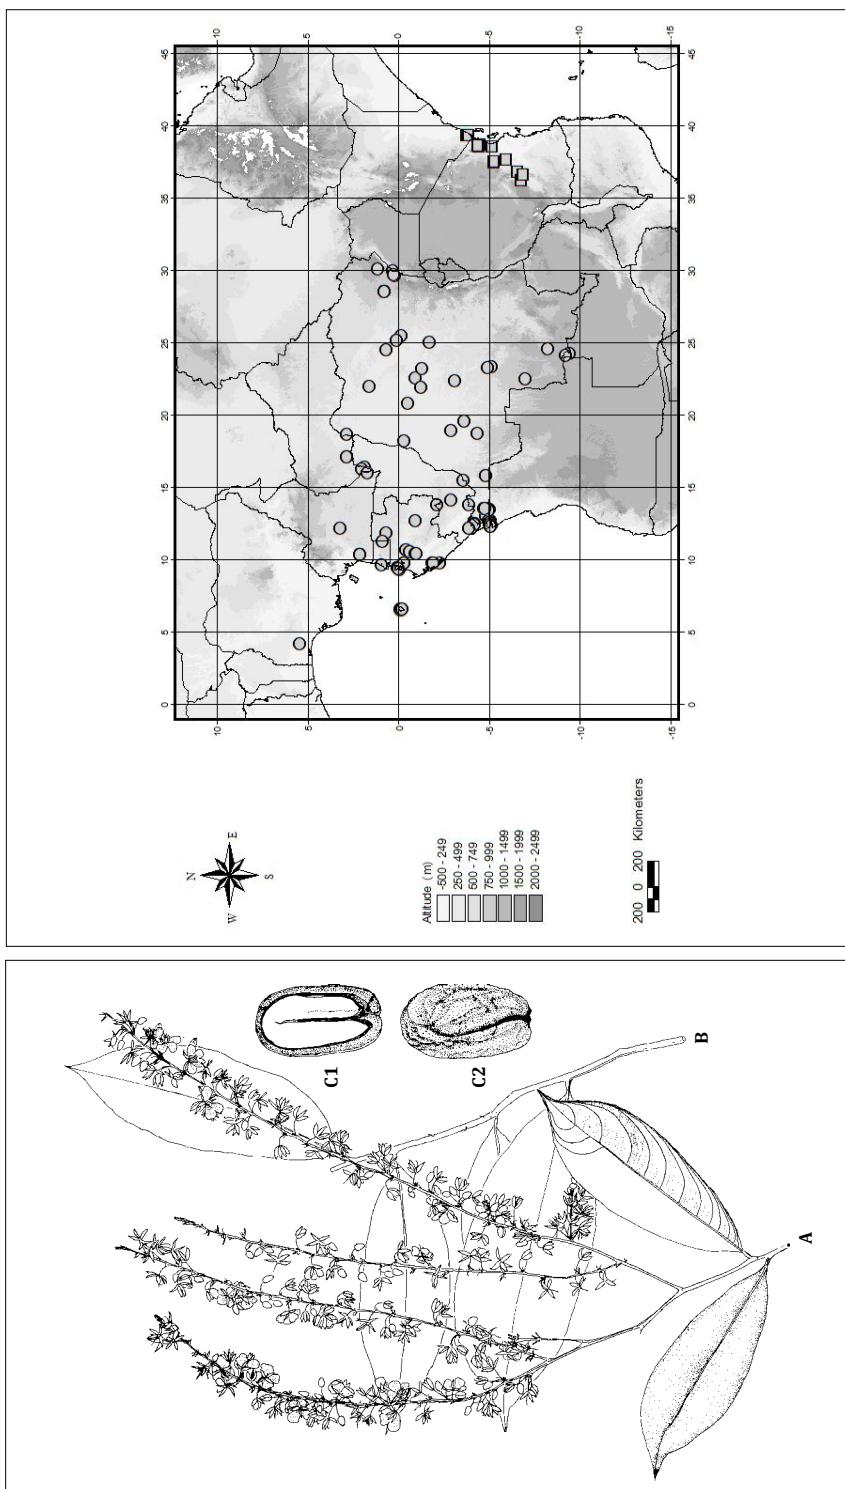

Figure 22. *Campylospermum plicatum*. A. Flowering branch. B. Sterile branch. C1 Seed, longitudinal section. C2. Seed. Drawings by Sabine Bousani
Map 25. Distribution of *Campylospermum plicatum* (○) and *Campylospermum saculeii* (□)

this name indicates the same taxon as *C. plicatum*.

Distribution: Cameroon, southern Central African Republic, Sao Tomé and Príncipe, Equatorial Guinea, Gabon, Republic of the Congo, Angola (Cabinda), Democratic Republic of the Congo, and north-western Zambia (**Map 25**).

Ecology: primary and secondary rain forest, gallery forest, swamp forest, along mangroves; on sandy and brown clay soils; at up to 940 m altitude.

Phenology: flowering and fruiting all year around.

Vernacular names: Democratic Republic of the Congo: Amamambamamba (Bila), Iliangeta (Kirega), Kosaka (Lingala), Nkolos (Lombole) and Waka (Yambata); Angola: Libambo, Tchitunga.

IUCN conservation status: LC. EOO=3,201,990 km², AOO=2,859,950 km², locations=84 (cell width=304 km). This species is widespread in Central Africa and well represented in herbaria indicating it is not uncommon. It is found in National Parks such as Loango and Pongara in Gabon, Monte Alén in Equatorial Guinea, Dzanga-Sangha in the Central African Republic and the Okapi Forest Reserve in the Democratic Republic of the Congo. Therefore, the category of Least Concern is most appropriate.

Tree or treelet, up to 20 m tall, bole up to 35 cm, with branched trunk; twigs with whitish brown bark. *Stipules* caducous, **triangular**, **2–13 mm** long. *Leaf*: petiole 2–10 mm long; leaf blade **narrowly elliptic or sometimes narrowly elliptic-obovate**, **(5–)10–17(–23) x (1.5–)3–5(–8) cm**, ratio **(2.5–)3.0–6.8**, base cuneate, **apex acute to slightly acuminate**, papyraceous to coriaceous, not or rarely slightly bullate, **margin serrulate, often indistinctly so**, sometimes entire towards the base, slightly glossy dark green above, glossy medium green below; venation: midrib prominent on both sides, main lateral veins **7–17 on either side, 6–22 mm apart**, prominent above, slightly to not prominent below, at a ± right angle with the midrib but curved upwards to run parallel to the margin, intermediate lateral veins 0 to 2, distinct on both surfaces, **tertiary venation scalariform along the margin but reticulate towards the midrib, usually very distinct on both sides and below markedly darker than the surrounding leaf mass**. *Inflorescence* terminal, occasionally 3 to 4 panicles grouped together, branched

or rarely unbranched, lax, its main axis **(4–)11–17(–28) cm long**; pairwise scales at the base of the peduncle absent or rarely persistent; racemes (0–)1–5, (1.5–)4–13(–21) cm long, **erecto-patent**; cymules 0.5–3 cm apart, 1–8-flowered; bracts caducous, triangular, up to 4 mm long. *Flower*: pedicel **(3–)6–10(–18) mm** long, articulated at **1–3 mm** from the base; sepals narrowly ovate, (4–)6–8 x 2–4 mm in flower, (5–)6–9 x 2–5 mm in fruit, apex acute; petals obovate, 5–13 x 3–10 mm, base cuneate, apex rounded to slightly emarginate; stamens: anthers 3–6 mm long; ovary c. 1 mm high; style 3–5 mm long. *Fruit*: receptacle c. 1 mm high in flower, 3–5 x 3–5 mm in fruit; drupelets **3 to 4** well developed per receptacle, **ellipsoid**, 6–9 x 5–6 mm; cotyledons **incumbent**, **dissimilar in size with a small outer cotyledon**.

Notes: Farron (1965) treats the taxon described as *Gomphia turnerae*, and recognized as a distinct species in for example the Flora of West tropical Africa, as a variety of *C. reticulatum* without providing a foundation for this transfer. In his contribution to the Flore du Congo, du Rwanda et du Burundi (Farron, 1967), he provides a key to the two varieties showing they are distinguished mainly by the coloration of the leaves when dried. Those of var. *reticulatum* stay more or less green after drying, whereas those of var. *turnerae* turn brownish. We think, however, that the coloration of the leaves may, amongst others, depend on the way in which the plants are dried (quickly or after having been preserved using the Schweinfurth method) and thus on its own this cannot be considered as a good character to distinguish taxa. Then, Bamps & Farron (1967), provide an additional character: leaves of var. *reticulatum* are papyraceous and those of var. *turnerae* are papyraceous to coriaceous, so no clear difference either. Finally, from a comparison of the two descriptions it seems that var. *reticulatum* has stipules of 1–3 mm long, while those of var. *turnerae* are 5–6 mm, but again, we observed stipule length to be highly variable and not related to the other characters mentioned. Therefore, we decided not to recognize the two varieties distinguished by Farron.

C. reticulatum is a widespread and highly variable species. According to the information on herbarium labels, it can be a treelet or a big tree with boles up to 30 cm dbh. The leaves can vary from narrowly elliptic to elliptic (ratio (2.5–)3.0–6.8) and the inflorescence varies from robust to slender. *C. reticulatum* is especially similar to *C. laxiflorum* and *C. warneckeii*; see below those species for the distinctive characters.

Distribution: from Senegal to south-western Ghana and in southern Nigeria, Cameroon, southern Republic of Central Africa, Equatorial Guinea, Gabon, Republic of the Congo, Democratic Republic of the Congo, Angola (Cabinda and northern) and southern Uganda (**Map 26**).

Ecology: in primary and secondary rain forest, gallery forest, along streams, and in swamp forest; predominantly on sandy, lateritic, clayey or clayish-loamy soil; at 0–1750 m altitude.

Phenology: flowering and fruiting all year round.

Map 26. Distribution of *Campylospermum reticulatum* (○) and *Campylospermum scheffleri* (□)

Vernacular names: Central African Republic: Mo Engé (Bambenjele). Democratic Republic of the Congo: Amamambamamba (Bila), Akpala (Yambata); Bolili bo kikereke, Inaolo a olili, Bompompongo, Yeka olili ikekereke (turumbu); Egboru (Mangbetu); Kanko, Luhaha, Ndando, Nawarubanda (Kitembo); Kalenge (Kinyanga); Lofandzandzuku (Lokundu); Lukako (Kinande); Ngulu (Kirega); Payagu (Mungutu); Soti (Kibubu); Bonion (Boyeka); Dande (Dundusana); Ebombo kasa sisi, Egbogbo, Kpoyo na mai, Ngeba na mai (Babua); Kamasonge (Lulua); Kimbengi (vallée de la Singa); Lopailondjo (Lac Tumba); Lufete (Djombo); Luvamba, Tumbu ya maza (Luki); Muliangulu (Tshiluba); Tumbulabenzo (Dima).

Uses: The bole is used as fire wood and timber (Farron 1967).

IUCN conservation status: LC. EOO=6,235,480 km², AOO=7,676,810 km², locations=367 (cell width=533 km). This species is widely distributed and has been frequently collected so seems to be fairly common. It occurs both within and outside protected areas. Therefore, the category of Least Concern has been assigned.

Specimens examined:

ANGOLA, Cabinda: nos arlas da floresta de Buco Zan-Maiombo. 4°46'S 12°33'E, 14 October 1916 (fl, fr), Gossweiler 6741 (COI,LISC); Belize. 4°39'S 12°46'E, 23 November 1918 (fl, fr), Gossweiler 7570 (BM,COI,K,LISC); Maiombe, Nkanda Mbaku, proximum Flumem, Luali-Chiloango. 4°47'S 12°32'E, 1923 (fl), Gossweiler 9015 (BM,LISC); **Cuanza Sul:** Cuanza Sul. Fundaô-amboim. 10°51'S 14°22'E. Alt: 900m, 11 July 1937 (fl), Exell 3168 (BM,COI); Cuanza Sul. Fundaô-amboim. 10°51'S 14°22'E. Alt: 900m, 11 July 1937 (fr), Exell 3169 (COI); Zôa-Amboim. 10°56'S 14°29'E, 3 July 1908 (fl), Gossweiler 4472 (BM,COI,K).

CAMEROON, Central Province: Mont Kala, 18 km route Younde-Edea. 3°52'N 11°21'E, 31 December 1969 (fl, fr), Mezili 164 (K); Massif du Mbam Minkom à l'est de Nkolakié (20-25 km NW de Yaoundé). 3°57.60'N 11°22.22'E. Alt: 788m, 27 May 2009 (fl, fr), Lachenau 869 (BR,WAG,YA); Mont Meza. 4°17'N 12°08'E, 12 May 1959 (fl, fr), Letouzey 1950 (P); E of Libamba College, approximately 9 km E of Makak. 3°33'N 11°07'E. Alt: 600m, 9 June 1987 (fl, fr), Manning, S.D. 1999 (K,MO,WAG); Eloumden mountain, 9 km SW. of Yaoundé. 3°49'N 11°26'E. Alt: 1165m, 29 December 1961 (fl), Breteler 2333 (BR,K,LISC,P,U,WAG,YA); Eloumden mountain, 9 km SW. of Yaoundé. 3°49'N 11°26'E. Alt: 1165m, 29 December 1961 (fl), Breteler 2334 (A,BR,FI,K,LISC,M,P,SSL,U,UC,WAG,YA,Z); Nkolbisson, 7 km W. of Yaoundé. 3°53'N 11°27'E. Alt: 800m, 3 March 1965 (st), Leeuwenberg 5008 (WAG); 60 km SW of Eséka, 12 km W. of Songbong. 3°26'N 10°24'E. Alt: 200m, 10 March 1965 (st), Leeuwenberg 5077 (BAS,WAG); 49 km SW of Eséka, right bank Nyong R. 1 km N. of Songbong. 3°28'N 10°30'E. Alt: 200m, 12 March 1965 (st), Leeuwenberg 5135 (WAG); 13 km N. of Lobo, 40 km NW of Yaoundé. 4°00'N 11°14'E. Alt: 700m, 13 April 1965 (st), Leeuwenberg 5433 (BAS,BR,P,WAG,YA); Hill near Nkolbisson, 7 km W. of Yaoundé. 3°52'N 11°27'E. Alt: 1000m, 6 July 1965 (st), Leeuwenberg 6054 (WAG); M'Bafia. 4°45'N 11°14'E, 19 December 1957 (fl, fr), Wit, H.C.D. de 7193 (WAG); 3°52'N 11°31'E, January 1914 (fl), Mildbraed 7887 (K); Sanaga und Djerem. Etwa 115 Km NO Jaunde. 4°37'N 12°15'E, February 1914 (fl), Mildbraed 8252 (K); Youngue près Ndom, à 40 km au Sud de Ndikinimeki (feuille IGN. 1/200000 Ndikinimeki). 4°25'N 10°49'E, 10 December 1971 (fl), Letouzey 10734 (K,P); **East Province:** Bertoua-Batouri. 4°30'N 14°00'E, 1960 (fl), Vroumsia 60 (P); Along Sanaga river S. of Goyoum, 20 km W. of Deng-Deng. 5°12'N 13°23'E. Alt: 635m, 27 January 1961 (fl), Breteler 945 (WAG); Road from Bangbel to Badzéré, near Bouba. 5°46'N 14°23'E. Alt: 980m, 1 March 1961 (fl), Breteler 1178 (BR,K,LISC,P,WAG); Bertoua, 5 km along road to Batouri, junction of road to Bétaré Oya. 4°35'N 13°44'E. Alt: 670m, 14 March 1961 (fl, fr), Breteler 1195 (BR,FI,K,LISC,M,P,WAG,YA); 2 km from Nguélémendouka, along road to Bika, near river Bam. 4°24'N 12°56'E. Alt: 700m, 15 November 1961 (fr), Breteler 2035 (WAG); rive de la Sanaga, près Goyoum. Feuille IGN. 1/200 000 Deng Deng. 5°12'N 13°22'E, 27 January 1961 (fl), Letouzey 3272 (P); Bertoua to Betare Oya. 36 miles from Bertoua. 4°56'N 13°50'E, 11 March 1969 (fl), Sanford, W.W. 6154 (K); Dengdeng. 5°10'N 13°35'E, (fl), Mildbraed 8818 (BM,K); **Littoral:** Abo. 4°11'N 9°45'E, 1874 (fr), Buchholz s.n. (HUH); 5km S of Nkongsamba, W slope of Mt. Nlonako. 4°55'N 9°56'E. Alt: 1000m, 17 December 1980 (fl), Beentje 1478 (BR,MO,WAG); Mont Nlonako, flanc NW. 4°55'N 9°57'E. Alt: 1400m, 25 December 1967 (fl, fr), Bamps 1571 (BR); route Douala-Edea, près du km 28. 3°58'N

9°57'E, 18 January 1962 (fl), *Letouzey* 4017 (P); 8 km W. of Masok. 4°08'N 10°24'E. Alt: 400m, 27 March 1965 (st), *Leeuwenberg* 5228 (WAG); on Dicam trail from Bekob camp. 4°21.04'N 10°24.90'E. Alt: 910m, 10 March 2007 (fl), *Wieringa, J.J.* 5888 (K,MO,WAG); Mt. Nlonako, near Nkongsamba. 4°55'N 9°57'E. Alt: 1400m, 3 December 1971 (st), *Leeuwenberg* 8795 (BR,K,WAG); Manengouba Mts., 4 km WNW of Nkongsamba. 4.58 N 9.53 E. 4°58'N 9°53'E. Alt: 1200m, 4 April 1972 (fr), *Leeuwenberg* 9548 (BR,FHI,HBG,K,LISC,MO,P,PRE,UPS,W AG,YA); près Lafi (=Ndocksamba) sur route Bafang-Yabassi, à 12 km au NNE de Nkondjok. 3°58'N 10°37'E, 6 February 1972 (fl), *Letouzey* 11139 (BR,K,WAG); 8 KM Est de l'embourchure de la Sanaga (Sud de Ngola). 4°46'N 13°10'E, 5 January 1974 (fl), *Letouzey* 12568 (BR,K); **South Province:** Kribi. 2°57'N 9°54'E, 14 March 1928 (fl), *Hédin, L.* 5 (P); 4 km NE Ebimimbang. 3°05'N 10°32'E. Alt: 500m, 27 February 1997 (fl), *Gemerden* 19 (WAG); Ngongonjie hill, near Akonetey S of Ebolowa. 2°30'N 11°08'E. Alt: 730m, 16 January 1978 (fr), *Koufani* 51 (P); Mimfia. 3°04'N 10°23'E, August 1913 (fl), *Zenker* 367 (B,C,G,HUH,LD,LY,WAG); Efulen, Bule country. 2°50'N 10°35'E, October 1895 (fl), *Bates, G.L.* 410 (E,G,K); Bitya, near the River Ja. 3°01'N 12°22'E, (fr), *Bates, G.L.* 1741 (K); 31 km ESE of Kribi, 1 km N of Ndjantom. 2°49.3'N 10°09.6'E. Alt: 100m, 15 February 1994 (fl), *Wieringa, J.J.* 2221 (WAG); 2 km S of Kribi, Grand Batanga road. 2°55'N 9°54'E, (st), *Bos, J.J.* 2994 (WAG); Campo-Ma'an area, Mabiogo, Dipikar Island, along transect T1. 2°15.3'N 9°52.8'E. Alt: 20m, 18 September 2000 (fl), *Tchouto Mbatchou* 3051 (KRIBI,SCA,WAG,YA); Campo-Ma'an area, Massif des Mamelles. 2°34.0'N 9°57.0'E. ***Campylospermum sacleuxii* (Tiegh.) Farron**

Fig. 24

Bull. Jard. Bot. État Bruxelles 35: 401 (1965). – *Cercanthesum sacleuxii* Tiegh., J. Bot. (Morot) 16: 198 (June 1902). – *Ouratea sacleuxii* (Tiegh.) Beentje, Utafiti 1(2): 70 (1988). – *Gomphia sacleuxii* (Tiegh.) Verdc., Fl. trop. E. Africa, Ochnac.: 50 (2005). – Type: *Sacleux 1551* (holotype: P!; isotype: P!), Tanzania, Zanzibar, Ngourou, September 1894.

Tree up to 15 m tall, with branched trunk; twigs with brownish bark. ***Stipules persistent, fused and present on internode***, triangular, 5–8 mm long. ***Leaf***: petiole 3–6 mm long; leaf blade obovate to narrowly elliptic-obovate or narrowly elliptic-obspathulate, (12–)16–30(–33) x (4–)6–10(–13) cm, ratio 2.2–4.0, base **cuneate to rounded or subcordate**, apex **acute to acuminate**, parchmentaceous, slightly bullate, medium green above, paler green below, dull on both sides, margin **serrate, teeth ending in a dark tip**; venation: midrib flattened to slightly prominent above, sometimes sunken in the basal half, prominent below, main lateral veins 13–25 on either side, 6–25 mm apart, above prominent but often running through a gully due to the bullateness of the leaf, prominent below, making a slight angle with the midrib, **parallel at first but towards the margin slightly curved upward and often splitting into two nerves before reaching the margin**, intermediate lateral veins 0–2 in between each pair of main lateral veins, prominent on both sides, tertiary venation **scalariform, perpendicular to the main lateral veins**, distinct on both sides. ***Inflorescence axillary*** (sometimes subterminal and just below the small terminal bud), **unbranched**, lax, its main axis **flattened**, (7–)9–28(–39) cm long; pairwise scales at the base of peduncle persistent; cymules 0.5–1(–2) cm apart, 1–8-flowered; bracts **persistent, triangular, 2–3 mm long**. ***Flower***: pedicel 5–15(–20) mm long, articulated at 1–2 mm from the base; sepals **ovate**, in flower 6–7 x 2–3 mm, in fruit 7–8 x 2–4 mm, base **rounded**, apex **acute**; petals **obovate**, (8–)10–12 x 4–6 mm, cuneate at base, **rounded** at apex; stamens: anthers 6–7 mm long; ovary 1–2 mm long; style 7–10 mm long. ***Fruit***: receptacle c. 1 mm thick in flower, in fruit 2–3 mm; drupelets 1 to 2 well developed per receptacle, **ovoid**, 5–6 x 4–5 mm; cotyledons accumbent, similar in size.

Notes: This species is only known from southernmost Kenya and Tanzania and has the same distribution area as *C. scheffleri* (Engl. & Gilg) Farron. These two species also share a close resemblance in terms of leaf venation pattern and the axillary, unbranched and flattened peduncle. *C. sacleuxii* differs from *C. scheffleri* by its generally much longer inflorescence and broader leaves with an acute to acuminate (not rounded to obtuse) apex and scalariform (not mainly reticulate) tertiary venation being perpendicular to the main laterals.

Distribution: southern Kenya and Tanzania (Map 25).

Ecology: lowland forest, dry evergreen forest, riparian forest; at 40–1400 m altitude.

Phenology: flowers observed in January, April and from July to December; fruits observed from January to April, in June and from September to December.

IUCN conservation status: LC. EOO=29,114 km², AOO=29,458 km², locations=16 (cell width=54 km). Although this species has a comparatively limited area of distribution, there is a fair amount of herbarium specimens (30) which suggests it is not rare. Although we have not seen specimens collected in the last decade, several others originate from Forest Reserves such as Lunguza, Lukoga, Mtibwa in Tanzania and Shimba in Kenya. Therefore, the category of Least Concern seems most appropriate.

Specimens examined:

***Campylospermum scheffleri* (Engl. & Gilg) Farron**

Bull. Jard. Bot. État Bruxelles 35: 401 (1965). – *Exomicrum scheffleri* (Engl & Gilg) Tiegh., Ann. Sci. Nat., sér. 8, Bot. 18: 38 (June 1903). – *Ouratea scheffleri* Engl. & Gilg, Bot. Jahrb. Syst., 33: 262 (1904). – *Gomphia scheffleri* (Gilg) Verdc., Fl. trop. E. Africa, Ochnac.: 48 (2005). – Type: *Scheffler* 189 (holotype: B†; isotype: E!, EA!, K!, Z!), Tanzania, Derema, Ugamba, 1899.

Ouratea schusteri Gilg ex Engl., Pflanzenw. Afr. 3, 2: 389 (1921). – *Gomphia scheffleri* subsp. *schusteri* (Engl.) Verdc., Fl. trop. E. Africa, Ochnac.: 49 (2005). – Neotype (designated here): *Schlieben* 2825 (holotype: B!; isotypes: G!, LISC!, MA!, P!, Z!), Tanzania, Bezirk Morogoro, Uluguru Gebirge, NW Seite, October 18th 1932. **syn. nov.**

Gomphia scheffleri subsp. *taitensis* Verdc., Fl. trop. E. Africa, Ochnac.: 49 (2005). – Type: *Drummond & Hemsley* 4342 (holotype: K!; isotype: EA!), Kenya, Taita Hills, 8 km NNE of Ngerenyi, Ngangao, September 15th, 1953. **syn. nov.**

Tree up to 25 m tall, with branched stem; twigs with brownish bark. ***Stipules persistent***, triangular, 2–3 mm long. ***Leaf***: petiole 5–10 mm long; leaf blade elliptic to oblong-elliptic or oblong, **(4–)6–15(–20) x (2–)3–5(–7) cm**, ratio **2–4.5**, base **cuneate to rounded**, apex **obtuse to rounded**, parchmentaceous to coriaceous, not bullate, glossy green above, paler green below, margin serrulate to shallowly so; venation: midrib flattened above, prominent below, main lateral veins 13–20 on either side, 5–12 mm apart, slightly prominent above, prominent below, more or less at an oblique to right angle with the midrib and curved upwards toward the margin, intermediate lateral veins 0–1 in between each pair of main laterals, prominent on both sides, tertiary venation with few scalariform veins perpendicular to the midrib but otherwise reticulate, distinct on both sides. ***Inflorescence axillary, unbranched***, lax, its main axis 3–15 cm long, **flattened**; pairwise scales at the base of peduncle absent; cymules 1–2 cm apart, 2–6-flowered; bracts persistent, triangular, c. 1 mm long. ***Flower***: pedicel 6–11 mm long, articulated at 1–3 mm from the base; sepals elliptic, 3–5 x 2–4 mm in flower, 3–6 x 2–5 mm in fruit, base cuneate, apex acute; petals oblanceolate-oblong to obovate, 4–10 x 1–6 mm, base shortly clawed, apex obtuse to rounded; stamens: anthers 4–5 mm long; ovary c. 1 x 1 mm, style c. 4 mm long. ***Fruit***: receptacle c. 1 mm high in flower, 3 x 3 mm in fruit; drupelets 1 to 3 well developed per receptacle, ovoid, c. 7 x 6 mm; **cotyledons accumbent, similar in size**.

Notes: Verdcourt (2005) distinguished three subspecies based on the shape and size of the petals and the distinctness of the tertiary venation. After having studied all material available, we conclude that both characters are too variable, not constant even within

a subspecies, to be able to make a clear distinction within the material. The tertiary venation can even vary between duplicates of the same collection. Thus, we decided not to recognize Verdcourt's subspecies.

The name *Ouratea schusteri* was published without a reference to a specimen that could serve as the type. It does give "Uluguru, Lupanga" as the origin, but no specimen could be traced that bears this indication and was collected before 1921. We conclude that the original material was most likely destroyed during World War II in Berlin and were forced to select a Neotype. We opted for *Schlieben 2825* because it originates from the same mountain ridge, duplicates are present in at least six herbaria, and it comprises complete flowering material.

C. scheffleri is close to *C. sacleuxii*; see below that species for the distinctive characters.

Distribution: southern Kenya and Tanzania (**Map 26**).

Ecology: evergreen and deciduous forest, montane forest, swampy forest, on steep slopes, along streams and on shallow rocky soil; at 1400–2150 m altitude.

Phenology: flowering all year round; fruits observed from January to April and from September to December.

IUCN conservation status: LC. EOO=66,024 km², AOO=59,201 km², locations=34 (cell width=63 km). Although this species has a comparatively limited area of distribution, there is a fair amount of herbarium specimens (47) which suggests it is not uncommon. It is found in Udzungwa National Park in Tanzania in Forest Reserve such as Shagayu Uluguru, Ndundulu, Lutindi, Shagai in Tanzania and Taita hills in Kenya, and its most recent collection dates from 2011. Therefore, the category of Least Concern seems most appropriate.

Key literature: Dale & Greenway (1961), Farron (1963, 1985), Verdcourt (2005).

***Campylospermum schoenleinianum* (Klotzsch) Farron.**

Fig. 25

Bull. Jard. Bot. Etat Bruxelles 35: 402 (1965). – *Gomphia schoenleiniana* Klotzsch, Abhandl. Kön. Akad. Wiss. Berlin, 1856, Phys. Abhandl.: 238, tab. IV (1857). – *Monelasmum schoenleinianum* (Klotzsch) Tiegh., Ann. Sci. Nat., sér. 8, Bot. 18: 35 (June 1903). – *Ouratea schoenleiniana* (Klotzsch) Gilg, Bot. Jahrb. Syst. 33: 264 (1904). – Type: *Schoenlein* s.n. (holotype: B†). Lectotype (designated here): Tab. IV in Klotzsch, Abhandl. Kön. Akad. Wiss. Berlin, 1856, Phys. Abhandl.: 238 (1857).

Tree up to 10 m tall, rarely scrambling, with branched stem; twigs with brownish bark. **Stipules persistent**, triangular, 2–4 mm long. **Leaf**: petiole 0–5 mm long, stout; leaf blade elliptic-obovate to narrowly so or narrowly elliptic-spathulate, **(8–)12–33 x (2–)3–10.5 cm**, ratio **(2.3–)2.7–5.5** base **cordate to auriculate**, apex acute to acuminate, coriaceous to papery, not bullate, margin entire to serrulate, upper side glossy dark green, lower side bright green; venation: midrib flattened above, prominent in the basal half below, main lateral veins 20–30 on either side, **5–10(–15) mm apart, prominent to slightly so above, not prominent below**, at a ± right angle with the midrib and curved upwards, intermediate lateral veins **0–2 in between subsequent main ones**, not or slightly prominent above, tertiary venation scalariform and perpendicular to oblique to the main lateral veins, but reticulate towards the midrib, **distinct on both sides**. **Inflorescence** terminal, branched or rarely unbranched, **lax, slender, pendulous**, its main axis **(10–)12–27(–39) cm long**, cylindrical; pairwise scales persistent at the base of the peduncle, few, triangular, 2–5 mm long; racemes **(0–)1–7, (3–)13–20(–27) cm long**; cymules **5–20 mm apart, 1–6-flowered**; bracts persistent, c. 1 mm long. **Flower**:

pedicel 5–10 mm long, articulated at c. 2 mm from the base; sepals **ovate to narrowly ovate**, in flower 5–7 x 2–3 mm, in fruit 6–7 x 3, apex acute; petals **broadly obovate to broadly spatulate, 6–9 x 5–6 mm, truncate** at base, **rounded** at apex; stamens: anthers 4–5 mm long; ovary c. 1 mm long; style c. 4 mm long. *Fruit*: receptacle 5 mm thick; drupelets 2 to 5 well developed per receptacle, **broadly ellipsoid to globose**, 6–8 x 6–7 mm; cotyledons **incumbent, similar in size**.

Notes: The lax inflorescence carrying well-developed racemes readily distinguishes this species from the rest of the West African ones with a cordate to auriculate leaf base. Since the holotype has been destroyed in Berlin and no duplicates or other original plant material could be traced, we are forced to designate the accompanying plate, which should also be regarded as part of the original material (McNeill, 2012 (Melbourne Code): Art. 9.3), as the lectotype (McNeill, 2012 (Melbourne Code): Art. 9.12).

Distribution: Guinea, Sierra Leone, Liberia, Ivory Coast and south-western Ghana (**Map 27**).

Ecology: in primary and secondary forest, on gentle slopes, in inundated forest, in riverine and gallery forest; on sandy, loamy and lateritic soil; at 20–680 m altitude.

Phenology: mature flowers and fruits collected almost all year round.

Vernacular names: **Ivory Coast:** abbey (Naé).

Uses: In Ivory Coast, a decoction of the root-bark is taken in very small doses as a strong purgative (Burkill 1997)

IUCN conservation status: LC. EOO=346,655 km², AOO=424,416 km², locations=94 (cell width=117 km). This species is well represented in herbaria suggesting it is not uncommon. It is found inside and outside protected areas and has numerous recent collections. Therefore, the category of Least Concern has been assigned.

Tree, rarely scandent, **up to 10 m tall**, with branched stem; twigs with brownish bark. **Stipules** persistent, triangular, 1–3 mm. **Leaf**: petiole **2–7 mm** long, slender to fairly stout; leaf blade narrowly elliptic to elliptic or sometimes narrowly elliptic-obovate, **(5–)10–17(–21) x (2–)3–4.5(–5.5) cm**, ratio **2.4–3.7**, **base cuneate**, apex **acute to slightly acuminate**, parchmentaceous to coriaceous, not or rarely slightly bullate, margin **serrulate but entire toward the base**, glossy medium to dark green above, glossy paler green below; venation: midrib **prominent or slightly so on both sides**, main lateral veins 9–16 on either side, **4–15 mm apart**, prominent above, not prominent below, at a ± right angle with the midrib and curved upward, intermediate lateral veins 0–1 in between each pair of main laterals, tertiary venation scalariform or sometimes reticulate along the midrib, perpendicular to the midrib, **distinct on both sides**. **Inflorescence terminal** or rarely axillary, branched, lax, its main axis **(5–)10–19(–26) cm long**; pairwise **scales minute, persistent at the base of the peduncle**; racemes **1–5, 2–15(–26) cm long, held ± horizontally**; cymules **0.5–1 mm apart**, **1–3-flowered**; bracts **persistent**, triangular, 1–2 mm long. **Flower**: pedicel 4–13(–18) mm long, articulated at **1–3(–5) mm from the base**; sepals narrowly ovate, in flower 5–8 x 1.5–2.5 mm, in fruit 6–9 x 3–4 mm, coriaceous, base truncate, apex acute; petals **obovate, 6–11(–13) x 5–7(–11) mm, shortly clawed at base, rounded** at apex; stamens: anthers 3–6 mm; ovary c. 1 mm long; styles 4–6 mm long. **Fruit**: receptacle 3–5 mm wide; drupelets 1–3 per receptacle, ± **reniform to subglobose**, 5–6 x 4–5 mm; cotyledons **incumbent, ± similar in size**.

Notes: At first glance, *C. squamosum* specimens with poorly developed inflorescences may resemble *C. congestum* (which normally has unbrached inflorescences) in having an elliptic leaf blade, a serrulate margin and prominent main lateral veins. However, *C. congestum* can be easily distinguished because of its peculiar, very fine and parallel

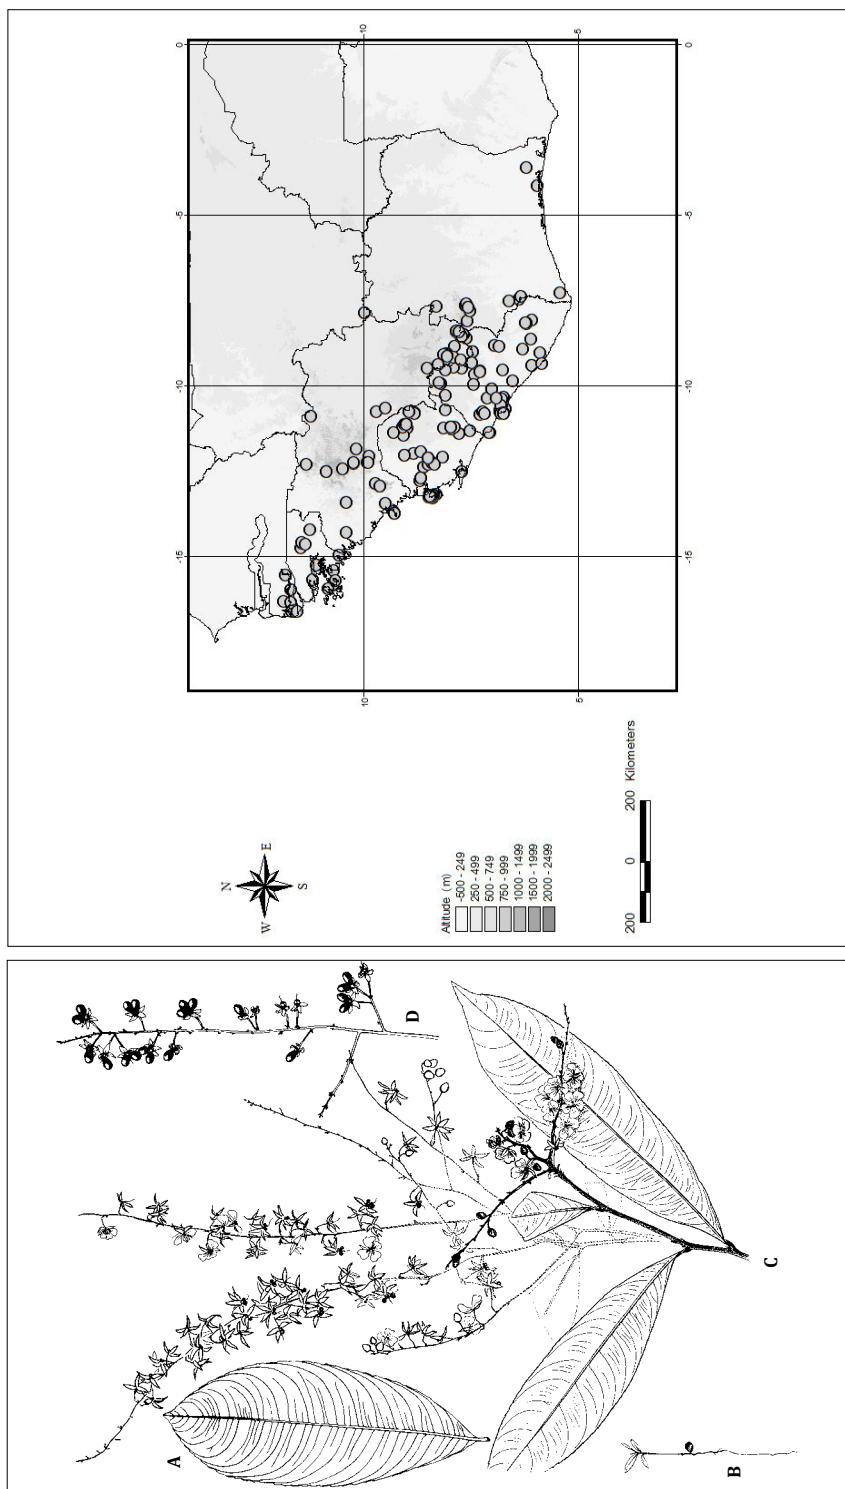

Figure 26. *Campylospermum squamosum*. A. Leafblade. B. Young plant. C. Flowering and fruiting branch. D. Fruiting branch. Drawings by Sabine Bousani
Map 28. Distribution of *Campylospermum squamosum*

tertiary venation. It also resembles *C. reticulatum*, but that species has dissimilar cotyledons (small outer cotyledon), a tertiary venation that is markedly darker than the surrounding leaf mass and caducous stipules that are generally much longer.

Distribution: from Senegal, Gambia, Guinea, Sierra Leone, Liberia and western Ivory Coast (**Map 28**).

Ecology: in primary and secondary forest, in gallery forest or rarely in palm tree forest, on slopes or along streams; on rocky and lateritic soil; at 15–1615 m altitude.

Phenology: flowering and fruiting all year round.

Vernacular names: **Sierra Leone:** Bunje, Etorai, Goboe, Yonibaua.

Uses: The young saplings are strong and very flexible. In Liberia, they are used to bind the drum-head on to hollow log drums, while the bark is used in poultices for topical application to areas of pain in the body (Burkill 1997).

IUCN conservation status: LC. EOO=605,770 km², AOO=629,176 km², locations=164 (cell width=162 km). This species is found inside National Parks such as Lofa and Sapo in Liberia and Taï in Ivory Coast. It is well represented in herbaria, suggesting it is not uncommon, and has several recent collections. Thus the category of Least Concern seems the most appropriate.

Specimens examined:

GUINEA, UNKNOWN: 1895 (fl), *Maclaude* 34 (P); Guinée Française. 1893 (fl), *Paroisse* 149 (P); french Guinea. (fl), *Farmar* 209 (BM,K); (fl), *Farmar* 227 (BM,K); **Boké:** 10°56'N 14°18'W, April 1899 (fr), *Paroisse* 45 (P); **Conakry:** surroundings Konakry. 9°31'N 13°43'W, (fl), *Lecerf s.n.* (P); Conakry. 9°31'N 13°43'W, (fl), *Maclaude s.n.* (P); Conakri. 9°32'N 13°41'W. Alt: 5m, 17 March 1902 (fl), *Debeaux* 309 (BM,K,P,US); Iles de Los. 9°31'N 13°43'W, February 1905 (fl), *Chevalier, A.J.B.* 12085 (LY); Ile de Los. 9°31'N 13°43'W, February 1905 (fl), *Chevalier, A.J.B.* 12103 (P); Ile de Los. 9°31'N 13°43'W, February 1905 (fl), *Chevalier, A.J.B.* 12117 (P); **Dinguiraye:** Sankaran. 11°58'N 10°53'W, (fl), *Pobéguin (Guinea series)* 827 (K,P); **Faranah:** Afrique occidentale, source du Niger. 9°05'N 10°45'W, 15 October 1944 (fl), *Jaeger, P.* 105 (P); Afrique occidentale, source du Niger. 9°05'N 10°45'W, 18 October 1944 (fr), *Jaeger, P.* 149 (P); Faranah ESE. 10°02'N 10°45'W, 30 March 1955 (fl), *Roberty* 17246 (G); cercle de Faranah. 9°47'N 10°38'W, 22 January 1909 (fl), *Chevalier, A.J.B.* 20479 (P); **Kindia:** Plantation de la Ouatama, bord de la Ouatamba (Friguiagbé). 9°57'N 12°56'W, 29 March 1937 (fr), *Chillou* 97 (WAG); Dalaba. 29 March 1939 (fr), *Chillou* 1205 (COI,K); French guinea: Friguiabé. 9°57'N 12°56'W, 26 April 1939 (st), *Chillou* 1292 (BR,P); Kakoulima. 9°46'N 13°27'W, February 1945 (st), *Schnell* 2460 (P); cercle de Kindia. 10°04'N 12°51'W, March 1905 (fr), *Chevalier, A.J.B.* 13109 (LY); Telimélé W. 10°56'N 13°25'W, 26 April 1955 (fr), *Roberty* 17627 (G); Telimélé W. 10°56'N 13°25'W, 26 April 1955 (fl), *Roberty* 17629 (G); **Labé:** Senegambia. 11°30'N 12°30'W, 1838 (fl), *Heudelot* 741 (BM,K); près de Fouta Djallon. 11°30'N 12°30'W, 1837 (fl), *Heudelot* 745 (BM,FHO,G,K,P); Senegambia. 11°30'N 12°30'W, 1837 (st), *Heudelot* 948 (K); Fouta Djallon. 12°05'N 12°18'W, December 1944 (st), *Schnell* 2326 (P); **Mamou:** Timbo. 10°38'N 11°50'W, February 1910 (fr), *Boué* 78 (G); environ de Pita. 11°02'N 12°26'W, December 1935 (fl), *Jacques-Félix* 674 (P); Konkouré. 10°17'N 12°14'W, 29 January 1885 (fl), *Pobéguin* 1140 (P); Fouta Djallon, 17 km of Dalaba. 10°43'N 12°16'W. Alt: 1006m, 6 March 1962 (fl, fr), *Langdale-Brown* 2630 (BR,K); Fouta Djallon, near Dalaba. 10°43'N 12°16'W. Alt: 1036m, 8 March 1962 (fl), *Langdale-Brown* 2637 (BR,K); Dalaba. 10°42'N 12°15'W, March 1950 (fl), *Schnell* 4658 (P); Mamou. 10°15'N 12°03'W, 10 February 1948 (fl), *Roberty* 10646 (G); Kouria. 10°19'N 12°15'W, 2 February 1906 (fl), *Chevalier, A.J.B.* 18196 (P); **Nzérékoré:** Bac du Diani. 7°45'N 8°49'W, 16 December 1957 (fl), *Bouquet, A. s.n.* (NEU); c. 2 km N of Kpaya 35 km NW of N'zérékoré. 7°59.78'N 9°02.34'W. Alt: 525m, 25 April 2011 (fl), *Koenen* 132 (WAG); 1.5 km N of Kpaya 35 km NW of N'zérékoré. 7°58.49'N 9°02.53'W. Alt: 530m, 25 April 2011 (fl, fr), *Koenen* 133 (WAG); 1.5 km N of Bowé. 7°47.52'N 9°09.92'W. Alt: 400m, 27 April 2011 (fr), *Koenen* 135 (WAG); East of Yomou. 7°34.6'N 9°14.6'W. Alt: 390m, 18 February 2012 (fl), *Yonon Botanic Team* 163 (WAG); Mt. Yonon. 8°04.01'N 9°03.68'W. Alt: 560m, 5 February 2012 (fr), *Simons, E.L.A.N.* 820 (MO,WAG); Mt. Yonon. 7°58.0'N 9°06.9'W. Alt: 681m, 6 February

2012 (fl), *Simons, E.L.A.N.* 824 (WAG); Ziama. 8°14'N 9°22'W, May 1945 (fl), *Schnell* 2627 (P); Nzérekoré, Mts Nimba. 7°37'N 8°25'W. Alt: 1250m, 7 January 1949 (fl), *Adam, J.-G.* 3131 (P); Macenta. 8°33'N 9°28'W, 13 January 1949 (fl), *Adam, J.-G.* 3276 (P); Nimba Mountains, between Camp 1 (Mifergui) and Zougué River. 7°41.8'N 8°23.8'W. Alt: 760m, 29 November 2006 (fl), *Jongkind* 7368 (WAG); Nimba Mountain. 7°37'N 8°25'W, 13 December 1949 (fl), *Adam, J.-G.* 7458 (P); Nimba Mountains, east slope of range. 7°39.25'N 8°22.58'W. Alt: 1475m, 16 June 2007 (fr), *Jongkind* 7692 (P,WAG); Forêt Classée de Mt Yonon. 7°59.6'N 9°05.1'W. Alt: 760m, 6 May 2011 (fr), *Jongkind* 10627 (WAG); Forêt Classée de Mt Yonon. 7°58.4'N 9°06.8'W. Alt: 640m, 14 May 2011 (fr), *Jongkind* 10789 (BR,WAG); Forêt Classée de Mt Yonon. 7°59.0'N 9°06.1'W. Alt: 770m, 21 May 2011 (fl), *Jongkind* 10896 (BR,G,MO,P,WAG); Nimba. 7°32'N 8°32'W. Alt: 1200m, 20 May 1970 (fl), *Adam, J.-G.* 25583 (K); Nimba Mountains, plot JRTH01, both sides of the road between Mifergui cité 1 and cité 2. 7°41.82'N 8°23.62'W. Alt: 763m, 4 December 2007 (fl, fr), *Nimba Botanic Team JR* 1180 (WAG); Nimba mountains, plot WHHG20. 7°39.76'N 8°22.31'W. Alt: 1615m, 9 July 2008 (fl, fr), *Nimba Botanic Team WD* 733 (WAG).

GUINEA-BISSAU, Bafatá: Dandum. 12°13'N 14°35'W, March 1933 (fl), *Espirito Santo* 464 (COI); Bafatá, Dandum. 12°07'N 14°38'W, 21 April 1961 (fl), *Alves Pereira* 1810 (C,MA); Bafatá, Madina de Mamadú Alfa. 12°14'N 14°36'W, 3 December 1955 (fl), *Espirito Santo* 3748 (B,COI,K,WAG); Bafatá, entre Bafatá e Galo Maro. 12°15'N 14°45'W, 12 December 1955 (fl), *Espirito Santo* 3806 (COI,K,LISC,WAG); **Bijagós:** Arguipélago dos Bijagós, ilha de Canhabaque, ancoradouro da tabanca Indena. 11°17'N 15°49'W, 9 December 1995 (fl), *Vidigal* 265 (LISC); Bolama, sector de caravela. Ilha Formosa. Perto de Abu. 11°28'N 15°56'W, 26 April 2000 (fl), *Catarino* 759 (LISC,WAG); Bubaque-Pavaação. 11°17'N 15°50'W, 4 May 1945 (fl, fr), *Espirito Santo* 2015 (COI,K,WAG); environ du village Meneque. 11°14.00'N 15°42.30'W, 3 March 2004 (fl), *Malaisse* 15946 (BR); **Biombo:** Bissau, entro vóre Bijimita. 11°54'N 15°41'W, 29 March 1945 (fl), *Espirito Santo* 1900 (COI,K,WAG); **Bissau:** Prabis. 11°48'N 15°14'W, 3 March 1945 (fl), *Espirito Santo* 1851 (COI); 11°48'N 15°14'W, 9 March 1945 (fl), *Espirito Santo* 1859 (K,WAG); **Gabu:** entre Canjadudi et Ichetche. 12°00'N 14°12'W, 21 February 1951 (fl), *Espirito Santo* 2904 (COI); **Tombali:** Cantanhez, Mata de Cassacunda. 11°18'N 15°25'W, 2 June 1995 (fl), *Martins, E.S.* 1066 (LISC); Cacine. 11°08'N 14°57'W, 19 January 1962 (fl), *Alves Pereira* 2860 (MA).

IVORY COAST, Abidjan: Forêt Classée de la Yaya. 5°39'N 3°35'W. Alt: 80m, 27 November 1997 (fl), *Jongkind* 4084 (BP,FHO,IAGB,MO,WAG); Adiopodoumé. 5°20'N 4°07'W, 5 April 1970 (fr), *Farron* 7012 (P); **Danané:** Mont Nimba, au campement, 7°37'N 8°25'W, 7 February 1989 (fl, fr), *Gautier, L.* 1170 (CSRS,G); Mount Nimba. 7°37'N 8°25'W. Alt: 1250m, 13 December 1967 (fl, fr), *Geerling* 1688 (C,K,WAG); Sangouiné. 7°18'N 7°48'W, 22 January 1970 (fl), *Bamps* 2355 (BR); Momy, Mts des Dans, 40 km N of Danané. 7°23'N 8°05'W. Alt: 1100m, 30 January 1984 (fl), *Hepper* 7926 (K); **Guiglo:** Zagné. 6°09'N 7°31'W, 18 February 2001 (fl), *Bakayoko* 55 (G,WAG); 10 km S of Tai, E of Pauléoula. 5°49'N 7°23'W. Alt: 130m, 8 March 1959 (fl, fr), *Leeuwenberg* 3021 (K,WAG); Taï. 5°52'N 7°27'W, 17 March 1982 (fl), *Stäuble* 210/ 3 (G); Taï. 5°52'N 7°27'W, 4 March 1982 (fl), *Stäuble* 26/ 38 (G); Taï. 5°52'N 7°27'W, 6 March 1982 (fl, fr), *Stäuble* 67/ 75 (G); **Man:** Mont Tonkoui (Man). 7°27'N 7°39'W, 26 November 1956 (fl), *Wilde, J.J.F.E. de* 913 (WAG); Mont Tonkoui. 7°27'N 7°39'W, 18 January 1970 (fl), *Bamps* 2327 (BR); Mont Tonkoui, SW of Man. 7°27'N 7°38'W. Key literature: Farron (1963, 1985), Hawthorne & Jongkind (2006), Hutchinson, Dalziel & Keay (1954).

***Campylospermum subcordatum* (Stapf) Farron**

Fig. 27

Bull. Jard. Bot. État Bruxelles 35: 402 (1965). – *Gomphia subcordata* Stapf, J. Linn. Soc., Bot. 37: 88 (1905). – *Ouratea subcordata* (Stapf) Engl., Pflanzenw. Afr. 3, 2: 489 (1921). – Type: *A. Whyte s.n.* (holotype: K!), Liberia, Montserrado, Kakata, within 20 miles of Kakatown, 1904.

Treelet of up to 5 m tall, **monocaulous** or stem sparingly branched; bark brownish. **Stipules** caducous, triangular, 3–5 mm long. **Leaf:** petiole 0–5 mm; leaf blade **narrowly spatulate to narrowly elliptic-spathulate**, **18–62 x 5–14 cm**, ratio **4.0–5.6**, base narrowly cuneate to subcordate, apex blunt to shortly acuminate, not or slightly bullate, coriaceous, margin serrulate, the teeth with a black tip, glossy dark green above, paler green beneath; venation: midrib prominent on both surfaces, main lateral veins **25–35 on either side**, **7–20 mm apart**, prominent above, not prominent below, making a slight angle with the midrib, straight at first and near the margin curved upwards, intermediate lateral veins 0–2 in between the main ones, prominent or slightly so above, tertiary venation scalariform, **perpendicular to the mains lateral veins**, distinct to slightly so on both sides. **Inflorescence axillary**; peduncle **22–42 cm long**, **flattened, woody**, carrying **2(–4) subopposite leafy bracts** at its apex from which **2–5 racemes emerge**; leafy bracts oblong, 6–12 x 2–5 cm, base cordate to subcordate, apex acute; racemes **(3–)13–28(–35) cm long**; pairwise scales persistent at the base of the raceme, 2–3 mm long; cymules 3–18 mm apart, **1–8(–12)-flowered**; bracts absent. **Flower:** pedicel 5–20 mm long, articulating at 2–5 mm from its base; sepals ovate, in flower 7–8 x 3–4 mm, in fruit 9–11 x 4–7 mm, apex rounded; petals **broadly obovate**,

9–12 x 7–10 mm, **cuneate at base, rounded at apex**; stamens: anthers 4–6 mm long; ovary 1–2 high; style 5–6 mm long. **Fruit:** receptacle 5–8 mm wide; drupelets 2–4 well developed per receptacle, broadly ellipsoid, 6–8 x 5–7 mm; cotyledons **incumbent, dissimilar in size, with a small inner cotyledon.**

Notes: This is a very distinctive species, readily recognized by the long to very long leaves and peduncle carrying two apical leafy bracts and a small bundle of racemes. It is also reminiscent of *C. elongatum* and *C. klainei* by having a flattened peduncle, but it differs from both species by for example having leaves with a cuneate to sometimes subcordate base and the inflorescence being composed of a bundle of racemes.

Distribution: from Guinea, Sierra Leone, Liberia and southern half of Ivory Coast (**Map 29**).

Ecology: primary and secondary forest, swamp forest, along forest edges, lagoons and rivers; on sandy and loamy soil; at up to 715 m altitude.

Phenology: flowering all year round; fruits observed in January, February, May, July and from October to December.

IUCN conservation status: LC. EOO=416,074 km², AOO=357,017 km², locations=64 (cell width=124 km). This species has numerous recent collections that are found in Forest Reserves such as Yapo in Ivory Coast, Gola in Liberia and in the Nimba Mountains and classified Forest of Mont Yonon, both in Guinea. It is fairly well represented in herbaria suggesting it is not uncommon and thus the category of Least Concern seems justified.

***Campylospermum sulcatum* (Tiegh.) Farron**

Fig. 28

Bull. Jard. Bot. État Bruxelles 35: 403 (1965). – *Exomicrum sulcatum* Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 340 (1902). – *Ouratea sulcata* (Tiegh.) Keay, Kew Bull. 1953: 81 (1953). – Type: *Staudt* 606 (holotype: P!; isotype: COI!, G!, K!, S!, Z!), Cameroon, Johann-Albrechtshöhe, 1896.

Ouratea oliveriana Gilg, Bot. Jahrb. Syst. 33: 261 (1904). – *Campylospermum oliverianum* (Gilg) Farron, Bull. Jard. Bot. État Bruxelles 35: 400 (1965). -Type: *Johnston* s.n. (holotype: B†; isotype: K!). Nigeria, Cross River, January 1888. syn. nov.

Tree up to 9 m tall, with branched stem; twigs with brownish white bark. **Stipules persistent**, triangular, 4–13 mm long. **Leaf**: petiole 3–6(–7) mm long; leaf blade narrowly elliptic to narrowly elliptic-obovate or sometimes elliptic-obovate, **(6–)9–17(–21) x (2–)3–6(–7) cm**, ratio **2.3–4.2**, base narrowly cuneate to attenuate, apex acuminate, coriaceous to papyraceous, distinctly to slightly bullate, margin **serrulate to entire**, teeth without a black tip, dark green above, paler green below, glossy on both sides; venation: midrib **strongly prominent above, prominent below**, main lateral veins 10–16 on either side, **9–14 mm apart, generally sunken above**, prominent below or sometimes shallowly sunken, more or less at a right or slight angle with the midrib but curved upward to run parallel to the margin, intermediate lateral veins 0–1 between each pair of main laterals, tertiary venation **scalariform**, perpendicular to the midrib, **distinct above, less distinct below**. **Inflorescence** terminal, **unbranched or rarely with 1 raceme, compact**, its main axis 1–5(–8) cm long; pairwise scales at the base of peduncle persistent, often numerous, narrowly triangular, up to 12 mm long; cymules 3–7 mm apart, 1–7-flowered; bracts persistent, triangular, 2–3(–5) mm long. **Flower**: pedicel 7–13 mm long, articulated at 2–3 mm from the base; sepals ovate, in flower 8–10 x 3–4 mm, in fruit 10–12 x 5–6 mm and curved over the drupelets, coriaceous, base truncate, apex acute; petals elliptic to obovate, 10–13 x 3–8 mm, truncate at base, rounded or emarginate at apex; stamens: anthers 4–7 mm long; ovary c. 1–2 mm long; style 4–7 mm long. **Fruit**: receptacle in fruit 3–6 mm wide, red; drupelets 1 to 2 well developed per receptacle, ellipsoid to broadly so, 7–9 x 4–7 mm; **cotyledons incumbent, dissimilar in size with a small outer cotyledon**.

Notes: *C. oliverianum* is lumped into *C. sulcatum*. Both species share the bullate leaves and an unbranched, compact inflorescence. Farron (1985) already noted their close similarity, but kept them apart, using the petal shape to separate them. He describes *C. oliverianum* as having leaves with 10–15 pairs of main lateral veins, an inflorescence which is longer than wide and elliptic petals, whereas in *C. sulcatum* there are 6–10 pairs of veins, an inflorescence as long as wide and obovate petals. Since in fact the two states of all three characters are observed in specimens from both species identified by himself, we started to have serious doubts about their distinction. From a closer study of the variability we concluded the two taxa can not be separated. Therefore, the two are united here under the name *C. sulcatum*, the oldest one.

C. sulcatum is a very distinct species with its short, compact inflorescence and a bullate leaf surface. As such, it is highly reminiscent of some forms of *C. excavatum*, but that species often has a branched inflorescence, much narrower sepals and a much more pronounced tertiary venation.

Distribution: Liberia, Ivory Coast, Ghana, Nigeria, Cameroon, southernmost Central African Republic, Equatorial Guinea, Gabon and the Republic of the Congo (**Map 30**).

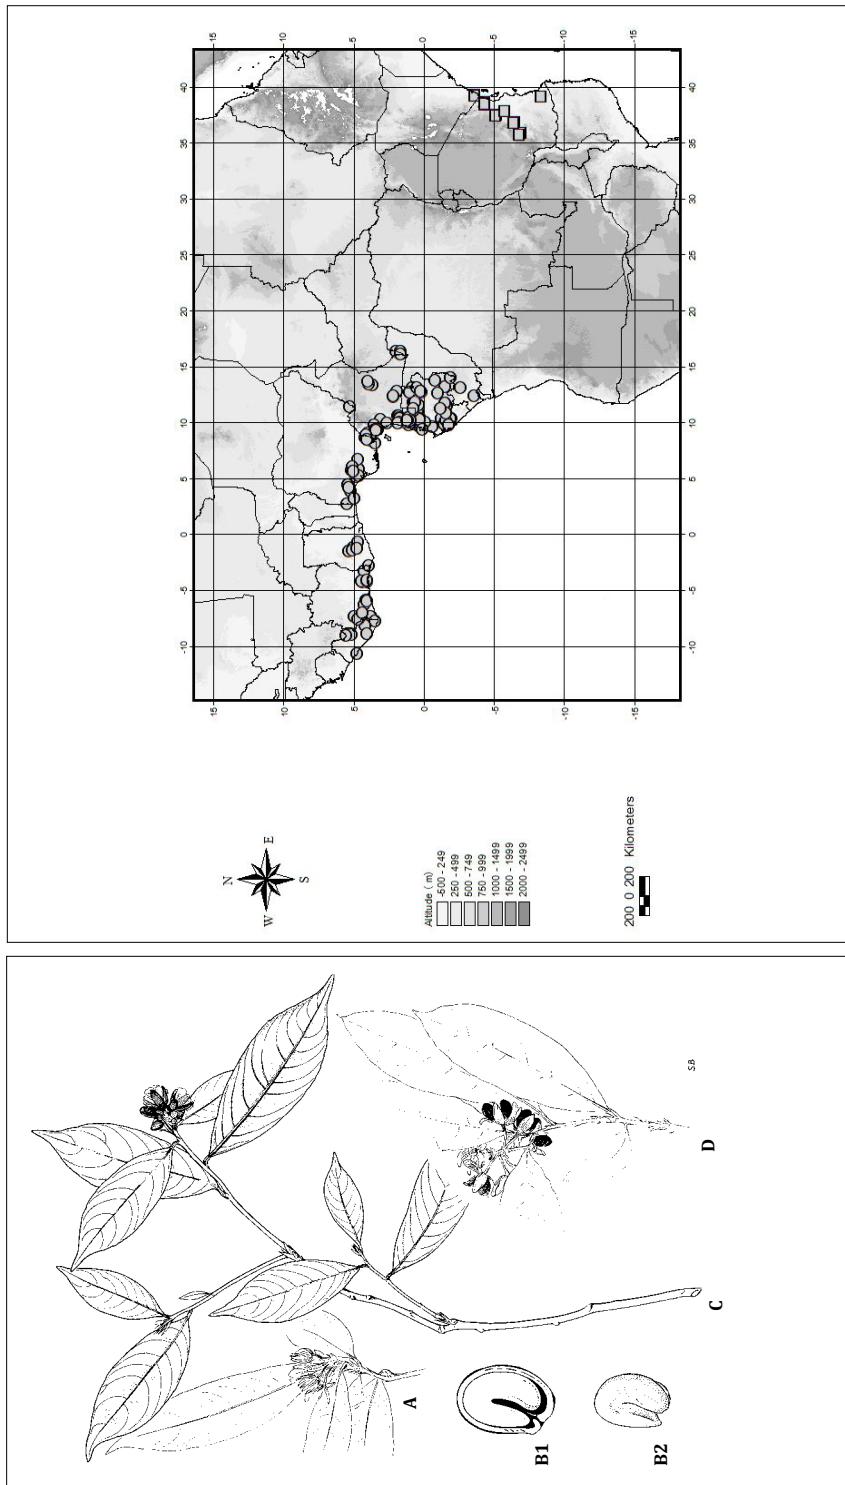

Figure 28. *Campylospermum sulcatum*. A. Flowering branch. B1. Seed, longitudinal section. B2. Seed, longitudinal section. C. Flowering branch. D. Fruiting branch.

Drawings by Sabine Bousani

Map 30. Distribution of *Campylospermum sulcatum* (○) and *Campylospermum warneckei* (□)

Ecology: primary and secondary forest, gallery forest, swamp forest, along rivers and streams; on clayey and sandy soils; at up to 960 m altitude.

Phenology: flowering and fruiting all year round.

Vernacular names: Benin: Agbda, Ishan-urohi (Urohi-Ogwa).

Uses: This is a decorative plant (Burkill 1997).

IUCN conservation status: LC. EOO=2,050,430 km², AOO=2,111,970 km², locations=161 (cell width=303 km). This species has a wide distribution and is found outside and inside National Parks such as Loango, Pongara, Minkebe in Gabon, Monte Alèn in Equatorial Guinea, Dzanga-Sangha in Central African Republic and also inside Forest Reserves such as Ekinta, Shasha and Urehi. It has numerous recent collection and thus the category Least Concern has been assigned.

***Campylospermum umbricola* (Tiegh.) Farron**

Fig. 29

Bull. Jard. Bot. État Bruxelles 35: 403 (1965). – *Monelasmum umbricola* Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 333 (Dec. 1902). – *Ouratea umbricola* (Tiegh.) Engl., Bot. Jahrb. Syst. 33: 259 (1904). – Type: Zenker 1792 (holotype: Pl; isotype: E!, G!, K!, P(2x)!, S!, WAG!, Z!), Cameroon, Bipindi, 1898.

Monelasmum macrophyllum Tiegh., Ann. Sci. Nat., sér. 8, Bot. 16: 334 (1902). – Type: Zenker 1848 (holotype: Pl; isotype: E!, G!, K!, Z!), Cameroon, Bipindi, 1898.

Tree up to 15 m tall, bole up to 20 cm, with branched trunk; twigs with brownish white bark. **Stipules** caducous, leaving a conspicuous scar at the base of the petiole, c. 10 mm long. **Leaf**: petiole 10–13(–15) mm long, **stout, canaliculate**; leaf blade obovate, **(24–)28–45(–53) x (8–)11–14(–17) cm**, ratio 2.5–3.9, base cuneate, apex acute to shortly acuminate, **coriaceous**, not to slightly bullate, glossy green above, paler green and less glossy below, margin regularly serrulate, entire toward the base; venation: midrib flattened above, prominent beneath, **2–3 mm wide towards the petiole**, main lateral veins (16–)23–26 on either side, 15–35 mm apart, slightly prominent but often running in a depression above, not to slightly prominent below, at a right to slight angle with the midrib but curved upward to run parallel to the margin, intermediate lateral veins 1–4 between each pair of main lateral veins, prominent on both sides, tertiary venation scalariform, perpendicular to oblique to the main lateral veins, indistinct above, slightly distinct below. **Inflorescence** terminal, branched, lax, its main axis (19–)22–40(–48) cm long, cylindrical; **pairwise scales at the base of peduncle absent**; racemes (3–)5–9, (9–)12–26(–30) cm long; cymules 0.5–3.5 cm apart, **1–12-flowered**; bracts caducous. **Flower**: pedicel (8–)10–15 mm long, articulated at 1–5 mm from the base, **strongly inflated in fruit**; sepals **ovate**, in flower 9–10 x 6–7 mm, **in fruit (20–)25–30(–35) x (10–)13–20(–25) mm**, **coriaceous**, base truncate, apex rounded, enclosing the drupelets; petals broadly obovate, **13–19 x 7–10 mm**, clawed at base, rounded at apex; stamens: anthers 5–6 mm long; ovary c. 2–3 mm long; style 5–6 mm long. **Fruit**: receptacle enlarged in fruit up to 4–5 mm thick; drupelets 2 to 3 well developed per receptacle, **ellipsoid**, 7–11 mm long, immature ones red, mature ones black; cotyledons

accumbent, more or less similar in size.

Notes: This species was previously only known from south-western Cameroon, but has now also been collected in the Crystal Mountains National Park, north-western Gabon. It is to be expected in Equatorial Guinea as well. *C. umbricola* is a distinct species, easily distinguished by the large and coriaceous leaves and by the sepals that are strongly enlarged in fruit.

Distribution: south-western Cameroon and north-western Gabon (Crystal Mountains) (**Map 29**).

Ecology: primary and secondary coastal forest, along streams; at 50–1000 m altitude.

Phenology: flowering from April to August; fruiting from June to July.

IUCN conservation status: NT B1/B2(iii,iv). EOO=51,361 km², AOO=26,892 km², locations=17 (cell width=52 km). This species has a disjunct distribution in Cameroon. Most of its locations are found outside of protected areas, some of which are under heavy environmental pressure of human populations and logging. Only one collection is from a protected area (Crystal Mountains National Park in Gabon). Therefore, the category of Near Threatened seems justified.

Tree up to 13 m tall, bole up to 7(–10) cm in diameter, with branched trunk; twigs with brownish white bark. *Stipules* caducous, **leaving a conspicuous scar at the base of the petiole**, triangular, 1–5 mm long. *Leaf*: petiole 2–5 mm long; leaf blade narrowly elliptic to narrowly elliptic-obovate or sometimes elliptic, **(7–)9–23(–27) x (2–)3–9(–10) cm**, ratio **(2.2–)2.4–3.7**, base cuneate to attenuate, apex acute to acuminate, coriaceous to papyraceous, not to slightly bullate, margin **serrate to serrulate**, medium green above, paler green below, glossy to dull on both sides; midrib prominent above, prominent to slightly so below, main lateral veins 10–25 on either side, 8–16(–20) mm apart, prominent on both sides, more or less at a right angle with the midrib but curved upward to run parallel to the margin, intermediate lateral veins 0–2 in between each pair of main laterals, prominent on both sides, tertiary venation **scalariform, perpendicular to the midrib, joined by cross veinlets**, distinct to slightly so above, distinct below. *Inflorescence* terminal, branched, lax, its main axis 3–14(–22) cm long, **compressed to flattened, zigzag**; pairwise scales at the base of peduncle absent; racemes **(1–)3–7, (2–)5–7(–13) cm long**; cymules **1–2 cm apart**, 2–7-flowered; bracts caducous, triangular, c. 1 mm long. *Flower*: pedicel 6–13 mm long, articulated at **3–7 mm from the base**; sepals narrowly ovate, in flower 5–8 x 1.5–3 mm, in fruit 10–15 x 5–6 mm and enveloping the drupelets, base rounded, apex acute; petals obovate, 3–10 x 3–6 mm, truncate at base, rounded to slightly emarginated at apex; stamens anthers 4–6 mm long; ovary c. 1 mm long; style 5–6 mm long. *Fruit*: receptacle c. 1 mm thick in flower, in fruit c. 3 mm; drupelets 1 to 4 well developed per receptacle, **ellipsoid to ellipsoid-oblong**, 7–10 x 5–6 mm; cotyledons **incumbent, dissimilar in size, with a small outer cotyledon**.

Notes: The varieties *C. vogelii* (Hook. f) Farron var. *poggei* (Engl.) Farron and *C. vogelii* (Hook. f) Farron var. *mollerii* (Tiegh.) Farron are lumped into *C. vogelii*. Farron (1965) does not state why he recognized these varieties, nor does he explain that in his 1967 or 1985 publications. From material identified by him, we conclude that var. *mollerii* has a more lax and slender inflorescence, a characteristic that we think is related to the environmental conditions in which the plant grows. Then, from the fact that in his Flore du Congo, du Rwanda et du Burundi treatment he only treats var. *poggei* (along with var. *costatum*, but see *C. costatum*) and writes this is found from Angola to Uganda, Kenya and Tanzania, we conclude that Farron treats the Central and East African material as being distinct from the typical West African var. *vogelii*. However, we failed to identify consistent characters to distinguish these geographical populations and thus decided not to recognize any varieties within *C. vogelii*.

C. vogelii can be easily confused with *C. reticulatum*, but it differs by having a compressed to flattened peduncle and inflorescence axis. *C. vogelii* has a scalariform tertiary venation

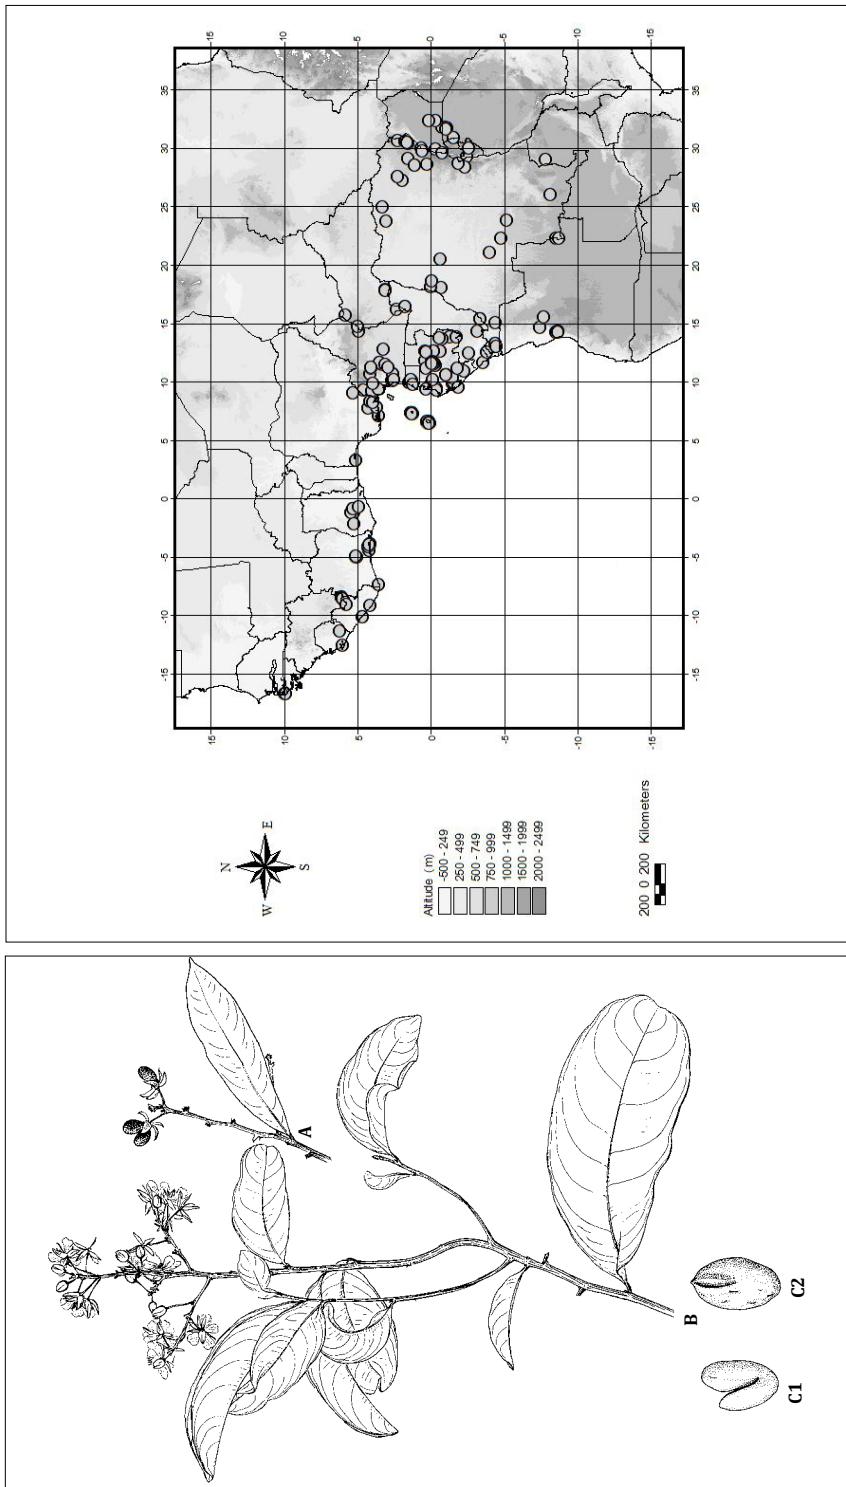

Figure 30. *Campylospermum vogelii*. A. Fruiting branch. B. Flowering branch. C1 & C2. Cotyledon. Drawings by Sabine Bousani
Map 31. Distribution of *Campylospermum vogelii*

which is perpendicular to the midrib and joined by cross veinlets.

Distribution: Sierra Leone, Guinea, Liberia, Ivory Coast, Ghana, Nigeria, Cameroon, southern Central African Republic, Equatorial Guinea, Sao Tomé & Principe, Gabon, Republic of the Congo, Angola, Democratic Republic of Angola, Uganda, Burundi, western Tanzania and northern Zambia (**Map 31**).

Ecology: primary or secondary forest, open understory forest, gallery and swamp area, forest, forest edges, coastal forest; on rocks along the sea-shore and white sandy soil; at up to 1800 m altitude.

Phenology: flowering and fruiting all year round.

Vernacular names: **Cameroon:** Okoga (Yaounde); **Central African Republic:** Mabungu (Lissongo); **Sao Tomé & Principe:** Café bravo; **Sierra Leone:** Tongane-le or Bue-le (Sherbro).

Uses: A decorative shrub with yellow flowers (Burkill 1997). The wood is reported to be used as firewood and timber (Farron 1967).

IUCN conservation status: LC. EOO=7,108,140 km², AOO=8,866,260 km², locations=179 (cell width=563 km). This species is widespread from West to Central and eastern Africa. It occurs in numerous protected areas, and therefore the category of Least Concern has been applied.

Key literature: Bamps & Farron (1967), Exell & Mendonça (1951), Farron (1963, 1965, 1985), Hawthorne & Jongkind (2006), Hooker & Bentham (1849), Johnston & Staph (1906), Robson (1963).

***Campylospermum warneckei* (Gilg ex Engl.) Biss.**

Blumea 58: 7 (2013). – *Ouratea warneckei* Gilg ex Engl., Veg. der Erde 9, Die Pflanzenw. Afr. 3, 2: 490 (1921). – Type: *Warnecke 468* (holotype: B, probably destroyed; isotype: BM!, E!, EA!, K!, Z!), Tanzania, Amani, 1907.

Tree to treelet, rarely scandent shrub, up to 15 m tall, with branched stem; twigs with whitish bark. *Stipules* caducous, triangular, 2–5 mm long. *Leaf*: petiole 2–5 mm long; leaf blade narrowly elliptic, **(9-)11-25 x (2-)3-6 cm**, ratio **2.9-5.7**, base attenuate, apex acute to slightly acuminate, **often with a sharp or mucronate tip**, papyraceous to coriaceous, not bullate, dark green above, medium green below, dull on both sides, margin serrulate but entire towards the base; venation: midrib prominent on both sides, main lateral veins 8–21 on either side, 7–15 mm apart, prominent above, slightly

3
p.228

prominent below, at a ± right angle with the midrib but curved upwards to run parallel with the margin, intermediate lateral veins 0–2 in between each pair of main laterals, less distinct, **tertiary venation scalariform, perpendicular to the midrib, with a pattern of very closely spaced cross-veinlets also predominantly perpendicular to the midrib**, distinct above, less distinct beneath. *Inflorescence* terminal or rarely axillary, branched, lax, its main axis (3–)11–19 cm long; pairwise scales at the base of peduncle absent; racemes 2–6, 3–13 cm long, **horizontal or slightly erecto-patent, thin but woody**; cymules 0.5–1 cm apart, 1–7-flowered; bracts triangular, c. 1 mm long. *Flower*: pedicel 8–15 mm long, articulated at 1–3 mm from the base; sepals ovate, 5–8 x 2–3 mm in flower, 6–8 x 3–4 mm in fruit, base rounded, apex acute; petals obovate, 5–13 x 5–8 mm, base cuneate, apex rounded to slightly emarginate; stamens: anthers 4–6 mm long; ovary c. 1 mm long; style 4–5 mm long. *Fruit*: receptacle enlarged to 5 x 4 mm in fruit; drupelets 1 to 4 well developed per receptacle, **ellipsoid to subglobose, 7–8 x 5–6**; cotyledons incumbent, cotyledons more or less similar in size.

Notes: We do not agree sinking this species into *C. reticulatum*, as suggested by Farron (1965) and Verdcourt (2005). *C. warneckei* has a typical scalariform tertiary venation, easily distinguished from the reticulate venation in the latter. Moreover, the cotyledons of *C. reticulatum* are distinctly unequal in size, with a much smaller outer cotyledon, while those of *C. warneckeii* are always more or less similar in size. This, in combination with the non-overlapping distribution of the two taxa, gives sufficient ground to recognize the taxon as distinct at species level. *C. warneckeii* is also close to *C. lunzuense* which differs in having spinulose-serrate leaves and pedicels generally articulating much further from the base.

Finally, Gilg (1921) does not refer to a specimen to serve as the obvious type of his name, but the text on the label of Warnecke 468 matches the data given in the protologue, making it clear that it should be regarded as the type.

Distribution: southernmost Kenya and Tanzania (**Map 30**).

Ecology: primary and secondary rain forest, moist submontane rain forest; at 250–1100 m altitude.

Phenology: flowering and fruiting from January to May and from September to December.

Uses: Food plant of *Hypolycaena buxtoni* (a butterfly; data from Congdon 569)

IUCN conservation status: LC. EOO=132,681 km², AOO=39,219 km², locations=21 (cell width=66 km). This species is represented in herbaria by a fair amount of specimens, suggesting it is not rare. It has numerous recent collections occurring in Forest Reserves such as Kwamkoro, Luhega, Magombera, Nkungwe, Udzungwa Scarp all in Tanzania, and Mwele and Shimba Hills in Kenya. Therefore, the category of Least Concern seems most appropriate.

Specimens examined:

Abstract

Ochnaceae s.str. (Malpighiales) are a pantropical family of about 500 species and 27 genera of almost exclusively woody plants. Infrafamilial classification and relationships have been controversial partially due to the lack of a robust phylogenetic framework. Including all genera except *Indosinia* and *Perissocarpa* and DNA sequence data for five DNA regions (ITS, *matK*, *ndhF*, *rbcL*, *trnL-F*), we provide for the first time a nearly complete molecular phylogenetic analysis of Ochnaceae s.l. resolving most of the phylogenetic backbone of the family. Based on this, we present a new classification of Ochnaceae s.l., with Medusagynoideae and Quiinoideae included as subfamilies and the former subfamilies Ochnoideae and Sauvagesioideae recognized at the rank of tribe. Our data support a monophyletic Ochneae, but Sauvagesieae in the traditional circumscription is paraphyletic because *Testulea* emerges as sister to the rest of Ochnoideae, and the next clade shows *Luxemburgia* + *Philacra* as sister group to the remaining Ochnoideae. To avoid paraphyly, we classify Luxemburgieae and Testuleeae as new tribes. The African genus *Lophira*, which has switched between subfamilies (here tribes) in past classifications, emerges as sister to all other Ochneae. Thus, endosperm-free seeds and ovules with completely, partly or for most of their length united integuments (resulting in an apparently single integument) are characters that unite all members of that tribe. The relationships within its largest clade, Ochnineae (former Ochneae), are poorly resolved, but former Ochninae (*Brackenridgea*, *Ochna*) are polyphyletic. Within Sauvagesieae, the genus *Sauvagesia* in its broad circumscription is polyphyletic as *Sauvagesia serrata* is sister to a clade of *Adenanarake*, *Sauvagesia* spp., and three other genera. Within Quiinoideae, in contrast to former phylogenetic hypotheses, *Lacunaria* and *Touroulia* form a clade sister to *Quiina*. Ancestral state reconstructions showed that monosymmetric flowers with adaptations to buzz-pollination (poricidal anthers), a syncarpous gynoecium (a near-apocarpous gynoecium evolved independently in Quiinoideae and Ochninae), numerous ovules, septicidal capsules, and winged seeds with endosperm are the ancestral condition in Ochnoideae. Although in some lineages poricidal anthers were lost secondarily, the evolution of poricidal superstructures secured the maintenance of buzz-pollination in some of these genera, indicating a strong selective pressure on keeping that specialized pollination system.

Keywords: Ancestral state reconstruction, Bayesian hypothesis testing, classification, ITS, Malpighiales, plastid markers

p.233

4.1 Introduction

The Malpighiales are one of the largest orders of flowering plants and are an important component of tropical rainforests worldwide worldwide (e.g., Gonmadje et al., 2011; Stropp et al., 2011). Its rapid diversification during the mid-Cretaceous made the order one of the phylogenetically most recalcitrant angiosperm groups (Davis et al., 2005; Wurdack and Davis, 2009). Additionally, the morphological foundation for patterns of relationships has been poor, following the massive restructuring that Malpighiales have undergone since the resurrection of the order as a consequence of molecular phylogenetics (e.g., Savolainen et al., 2000; Davis and Chase, 2004; APG III, 2009; Endress et al., 2013). Only recently, with the advent of phylogenomics (Xi et al., 2012) and the availability of extensive floral morphological data (Endress et al., 2013), could major progress in our understanding of the phylogenetic backbone and familial relationships be achieved. Nonetheless, some relationships still remain unresolved. One clade identified as in strong need for comprehensive molecular phylogenetic studies are Ochnaceae (Matthews et al., 2012; Endress et al., 2013).

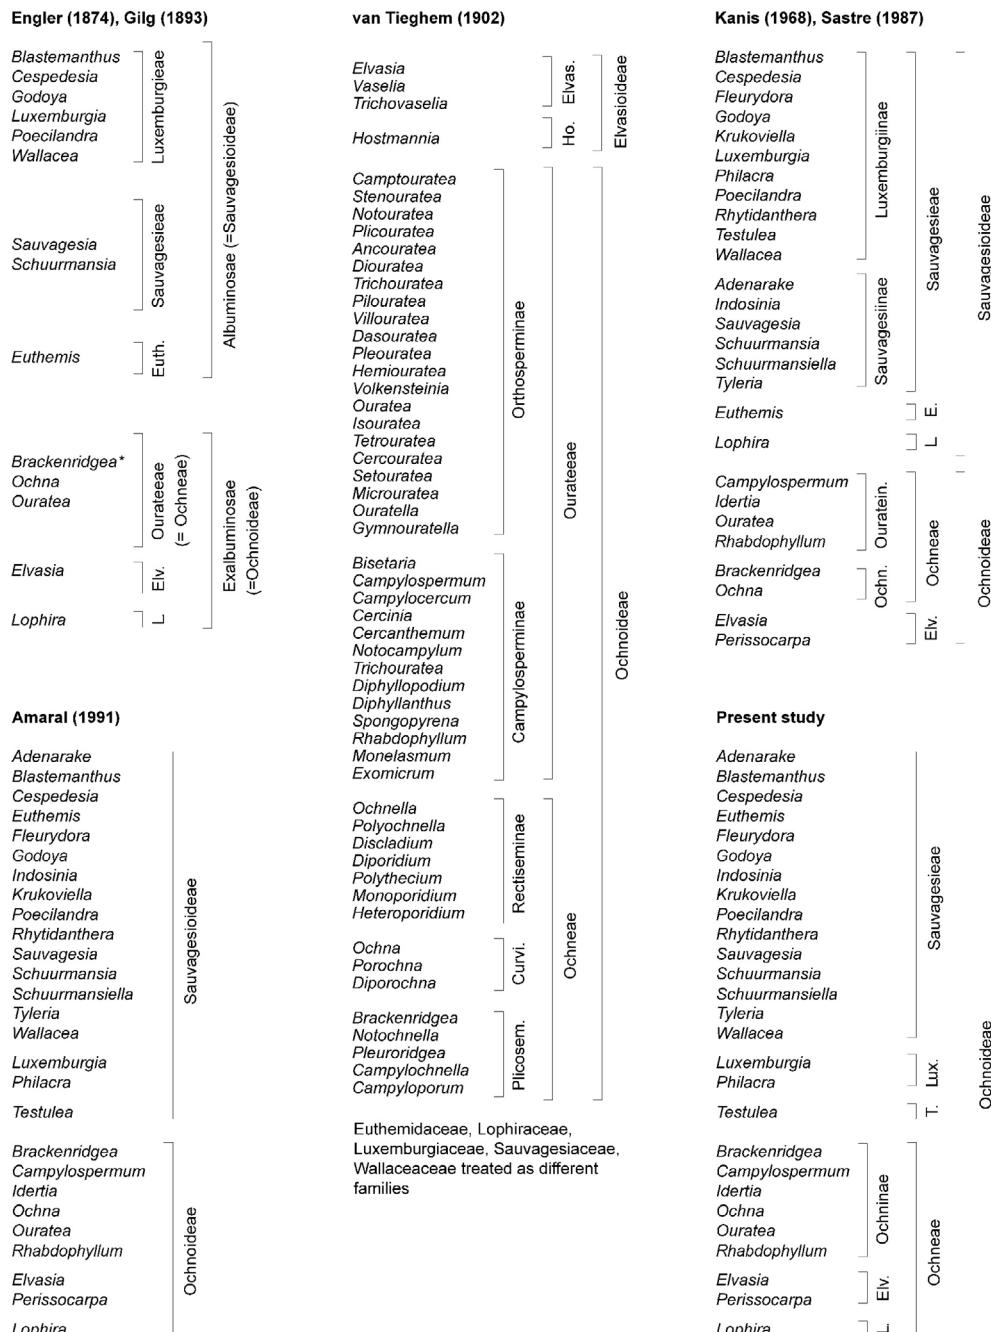

In higher-level molecular phylogenetic studies, Ochnaceae s.str. form a well-supported clade together with the monotypic Medusagynaceae – an endemic of the Seychelles – and the Neotropical Quiinaceae (Fay et al., 1997; Davis et al., 2005; Schneider et al., 2006; Korotkova et al., 2009; Bell et al., 2010; Soltis et al., 2011). In the most recent APG classification (APG III, 2009), all three were united to form an expanded Ochnaceae s.l. (if not specified, from here we refer to Ochnaceae s.str.). Nonetheless, some more recent studies keep all three as separate families because they form distinct clades that are also morphologically well-characterized (Wurdack and Davis, 2009, Matthews et al., 2012; Xi et al., 2012; Endress et al., 2013). The position of Ochnaceae s.l. within Malpighiales has been unclear until recently, when Xi et al. (2012) inferred that they are sister to the clusioid clade, though with low support (Bayesian posterior probability = 0.81). While higher-level relationships became clearer, molecular evidence for infrafamilial relationships of Ochnaceae is still wanting.

Ochnaceae in the traditional circumscription (Amaral, 1991; Amaral and Bitrich, in press) are a largely woody pantropical family, comprising ~500 species and 27 genera. The highest number of species is found in the Neotropics with 15 genera and about 300–350 species; Africa has nine genera and about 150 species, and the lowest diversity is observed in Southeast Asia, which is home to ~20 species and eight genera (Kanis, 1968; Sastre, 2003; Verdcourt, 2005). Ochnaceae occur in rain forests, dry forests and savannas, and some taxa develop fire-adapted forms (Kanis, 1968). Most Ochnaceae are shrubs or small trees and only few are herbaceous (species of *Sauvagesia* L.) or large trees of the canopy strata (e.g., *Brackenridgea* A. Gray, *Lophostoma* Banks ex C.F. Gaertn. and *Testulea* Pellegr.). The African genus *Lophira*, and to a lesser extent also *Testulea*, provide

valuable timber (azobé and izombé, respectively; Doumenge and Séné, 2012; Oduro, 2012). An important diagnostic character is the leaf venation with many Ochnaceae possessing rather densely spaced parallel secondary veins and the tertiary veins perpendicular to these. The number of sepals, petals, and stamens varies drastically across the family, but flowers are basically pentamerous. Potential synapomorphies of the family are poricidal anthers, stamen filaments with an abruptly narrow attachment zone of the anthers, and the crystal layer in the endostesta (Amaral, 1991; Matthews et al., 2012). The common poricidal anthers or the poricidal system (i.e., the pore is formed by the staminodes enveloping the functional anthers) are interpreted as adaptations to buzz-pollination (Kubitzki and Amaral, 1991). The best known feature, although only present in part of the family, are the fruits consisting of a swollen red receptacle bearing free black drupelets (resulting in the family's nick name, Mickey Mouse plants), but fruit type is widely variable in Ochnaceae s.str. (see, e.g., Dwyer, 1946).

Ochnaceae have traditionally been divided into subfamilies Ochnoideae and Sauvagesioideae – corresponding to Engler's "Exalbuminosae" and "Albuminosae" (Fig. 1), respectively – on the basis of the absence (Ochnoideae) or presence (Sauvagesioideae) of endosperm in the seeds (Engler, 1874; Kanis, 1968; Amaral, 1991). In most classifications, both subfamilies are subdivided into tribes and subtribes, but the concepts and circumscriptions have been controversial (Fig. 1). The majority of the genera of Sauvagesioideae are species-poor. The largest and morphologically most heterogeneous genus is *Sauvagesia* with about 35 species. By far the highest diversity is observed in tribe Ochneae which makes up more than two thirds of the species richness of the family, comprising the three most species-rich genera *Ouratea* Aubl. (~200 spp.; Sastre, 2003), *Ochna* L. (~80 spp.; Verdcourt, 2005), and *Campylospermum* Tiegh. (~50 spp.; Farron, 1985; Bissiengou et al., 2013) and the smaller *Brackenridgea* (9 spp.; Kanis, 1968; Callmander et al., 2010), *Rhabdophyllum* Tiegh. (8 spp.; Sosef, 2008), and *Idertia* Farron (4 spp.; Farron, 1985).

Ochnaceae are noteworthy for their complex biogeographical history with radiations in the Old and New World. The occurrence of both forest and savanna species in several genera also make Ochnaceae an excellent system for the study of forest-savanna transitions which have recently been used to address responses of rainforests to climate change and of climatic tipping points for tropical rainforests versus savannas (Hirota et al., 2011) or the reconstruction of the origin of these major tropical and subtropical biomes (Simon et al., 2009). Additionally, recent efforts to gain insights into the evolution of Ochnaceae using new floral morphological data (Matthews et al., 2012; Endress et al., 2013) further highlight the need for a sound molecular basis and an updated and stable classification of the family. The shifting circumscriptions and infrafamiliar classifications of Ochnaceae (s.str. and s.l.) hamper communication due to frequent changes and inconsistencies in floras and standard taxonomic and floristic databases worldwide.

p.235

Figure 1. Important classifications of Ochnaceae in a historical context, including the classification of the present study, showing the ranks of subfamily, tribe and subtribe. Asterisks indicate new additions or changes.^a *Gomphia* is a synonym of *Ouratea*, but in Kanis (1968) it was used for the palaeotropical Ourateinae: *Campylospermum*, *Idertia* and *Rhabdophyllum*. Van Tieghem's (1902) classification did not include "Sauvagesioideae". Curvi. = Curviseminae; Elv. = Elvasiae or Elvasiinae; E. or Euth. = Euthemideae; Ho. = Hostmanniae; L. = Lophireae or Lophirinae; Lux. = Luxembourgiae; T. = Testuleeae.

Our study aims at providing for the first time a molecular phylogenetic framework for a modern classification of Ochnaceae based on near-complete taxon sampling at the genus level and multiple DNA regions. Additionally, we examined evolutionary hypotheses for taxonomically important characters.

4.2 Materials and Methods

4.2.1 Taxon sampling

Plant material was obtained during field excursions, from herbarium specimens, or from the DNA banks at Kew (K), the Missouri Botanical Garden (MO), and the National Herbarium of the Netherlands (Wageningen branch, WAG). Our final taxon sampling contains 93 accessions of Ochnaceae s.l. (Table 1), comprising all genera of Ochnaceae s.str. – following the generic circumscriptions of Amaral (1991) –, except *Indosinia* J.E. Vidal and *Perissocarpa* Steyerm. & Maguire. In addition, the monotypic Medusagynaceae and all genera of Quiinaceae were included. Based on Xi et al. (2012), three representatives of the clusioid clade were chosen as outgroups. For the pantropical *Sauvagesia* and especially the genera of Ourateinae (*Campylospermum*, *Idertia*, *Ouratea*, *Rhabdophyllum*), several species per genus were sampled.

4.2.2 Character sampling

For the taxa mentioned in the previous section, we produced sequence data for five loci, viz. the plastid loci *matK*, *ndhF*, *rbcL*, *trnL-trnF* (including the *trnL* intron, *trnL* 3' exon and *trnL-trnF* intergenic spacer), and the nuclear ribosomal internal transcribed spacer (including ITS 1, 5.8 S, ITS 2).

For most taxa only herbarium specimens were available. Amplification and sequencing of samples from herbarium specimens often fails due to the highly degraded nature of the DNA (Särkinen et al., 2012). Thus, taxa represented only by such specimens may contain missing data. Excluding taxa, however, regrettably reducing taxon sampling, would negatively impact phylogenetic analyses as in general a reduced taxon sampling decreases phylogenetic accuracy, is more likely to introduce systematic error, and leads to a deterioration in parameter estimation in model-based methods (e.g. Rannala et al., 1998; Heath et al., 2008). In particular, our data set represents only 20% of the species diversity in Ochnaceae, and pruning incompletely sampled terminals might give rise to systematic error known as long branch attraction (Felsenstein, 1978; Graybeal, 1998; Kück et al., 2012). On the other hand, it has been shown that the accuracy of phylogenetic analyses is robust to the inclusion of incomplete taxa – even those with large amounts of missing data (Cho et al., 2011; Wiens and Morrill, 2011). Therefore, taxa with incomplete sequence data were included in our data set. In a few cases, adequate representation of taxa of interest was achieved by the combination of data from different collections

Table 1. Taxon list with information on herbarium vouchers (herbarium acronym), geographic location and GenBank accession numbers for five DNA regions. Data from additional accessions used in composite taxa are in parentheses; for cultivated material from Botanic Gardens (BG), the garden accession numbers are given.

(Campbell and Lapointe, 2009), thus forming composite terminals (but only combining sequences of different individuals of the same species; not forming composite genera, with the exception of the outgroup genus *Hypericum*; see Table 1).

4.2.3 DNA isolation, PCR, and sequencing

Genomic DNA was isolated from leaves of herbarium specimens or silica gel-dried leaves using different methods: (1) the DNeasy Plant Mini Kit (Qiagen) according to the manufacturer's protocol; (2) the CTAB method (Doyle and Doyle, 1987) with a precipitation time of up to one week for herbarium specimens; (3) the AnaP method with PTB (*N*-phenacylthiazolium bromide) as an additive as described in Telle and Thines (2008). Tissue (~2–20 mg dry weight; if available, also up to 100 mg) was ground to a fine powder by a Mixer Mill MM200 (Retsch, Haan, Germany).

Amplifications were carried out in 25 µl volumes with 1.25 U of MyTaq DNA polymerase (Bioline, London, UK), 1x MyTaq reaction buffer (containing 3 mM MgCl₂, 1 mM of each dNTP, stabilizers and enhancers), 0.3 µM of each primer, and undetermined quantities of genomic DNA template in a Mastercycler S (Eppendorf, Hamburg, Germany). Alternatively, amplifications were performed using MangoTaq of the same manufacturer as described previously (Telle and Thines, 2008). The following primer combinations were used initially: ITS-F1 & -R1; ITS 1/Leu & ITS 4; *matK*-400F & *trnK*-2R; *ndhF*-310F/331F & 2110R; *rbcL* aF & aR; *trnL*-F c & f (Table 2). If necessary, internal primers were used, and for some of the regions new primers were designed (Table 2). After initial denaturation (4:00 min at 94°C), polymerase chain reaction (PCR) was performed for 35 cycles of denaturation (0:20 min at 94°C), primer annealing (0:20 min at 54°C [ITS], 52°C [*matK*], 48°C [*ndhF*, *trnLF*], 55°C [*rbcL*])), and primer extension (0:30 min at 72°C). The reactions ended with an elongation period of 7 min at 72°C. PCR products were electrophoresed on 1% agarose gels in Tris-borate-EDTA buffer and stained with ethidium bromide. Afterwards, PCR bands were excised and purified with the Qiaquick gel extraction kit (Qiagen). Alternatively, unincorporated dNTPs and leftover PCR primers were directly removed in 20 µl reactions using 10 µl of the PCR product, 0.2 U Exonuclease I (New England Biolabs), 0.5 U Shrimp alkaline phosphatase (USB). This reaction mix was incubated for 20 min at 37°C and deactivated for 20 min at 80°C in a thermocycler. PCR products were mostly bidirectionally sequenced using the forward and reverse PCR primers (5 pmol) and the BigDye® Terminator v.3.1 Cycle Sequencing Kit (Applied Biosystems, Inc.) on an ABI 3730 xl capillary sequencer following the manufacturer's instructions. The edited DNA sequences were submitted to GenBank and accession numbers are listed in Table 1.

4.2.4 Sequence alignment and phylogenetic analysis

Sequence alignment was done with the program MAFFT, version 7.015b (Katoh et al., 2002; Katoh et al. 2009), using the L-INS-I algorithm with “maxiterate” set to 1000 (for ITS, the Q-INS-I algorithm); if necessary, the obtained alignment was subsequently adjusted manually. Alignment gaps (indels) were treated as missing data. The alignment was generally straightforward, except for the ITS region which contained several

highly variable parts. Ambiguous or hypervariable alignment positions were excluded manually (for the *trnL-F* region) or, for the ITS region, using the software Gblocks 0.91b (Castresana, 2000; Talavera and Castresana, 2007) with default settings.

Because of the large proportion of unequal taxon sampling between the five regions, topology-based incongruence tests (Shimodaira-Hasegawa test; Shimodaira and Hasegawa, 1999) are either impossible or, as in the case of the incongruence length difference test (Farris et al., 1994), prohibitively time-consuming. Instead, we performed ML analyses for each region separately as outlined below and searched for well-supported significant incongruence (e.g, Couvreur et al., 2010). Due to the lack of incongruence, the regions were combined following a supermatrix or total evidence approach (Eernisse and Kluge, 1993; de Queiroz and Gatesy, 2007). Data concatenation was done with the program SequenceMatrix, version 1.78 (Vaidya et al., 2011).

Tree searches were performed using maximum likelihood and Bayesian approaches. Prior to these analyses, the optimal substitution model was determined using Modeltest 3.7 (Posada and Crandall, 1998). Based on the Akaike Information Criterion (AIC), different substitution models were suggested for each of the analyzed regions: TrN+I+G for ITS, GTR+G for *matK*, TVM+I+G for *ndhF*, GTR+G for *rbcL*, and TVM+G for *trnLF*. Maximum likelihood analyses were carried out using RAxML (Stamatakis, 2006) and the raxmlGui 1.3 (Silvestro and Michalak, 2012), setting partitions for each region, the model to GTRGAMMA and the bootstrap (BS) analysis to 1000 replicates.

For the Bayesian analysis of the concatenated data, the same partitions were defined as for the RAxML analysis. Analyses were performed with MrBayes, version 3.1.2 (Huelsenbeck and Ronquist, 2001; Ronquist et al., 2012), employing a Markov chain Monte Carlo (MCMC) procedure in order to simultaneously estimate an optimal phylogenetic tree and the posterior probabilities (PP) of interior branches (Rannala and Yang, 1996; Li et al., 2000). Four parallel Markov chains, incrementally heated by a temperature of 0.2, were run for 10 million generations, sampling every five hundredth generation. Convergence of runs was tested by inspecting whether the standard deviation of split frequencies of the runs was < 0.01 and by using the effective sample sizes (ESS) as calculated with Tracer 1.4 (Rambaut and Drummond, 2007), considering ESS values >200 as good evidence. The first 2,500,000 generations were discarded, and a consensus tree calculated from the remaining trees.

Analyses were partially run on the Cyberinfrastructure for Phylogenetic Research (CIPRES Science Gateway; <http://www.phylo.org/index.php/portal/>; Miller et al., 2010). Phylogenetic trees were visualized in FigTree, version 1.4 (<http://tree.bio.ed.ac.uk/software/figtree/>).

4.2.5 Hypothesis testing

For a statistically based comparison between competing phylogenetic hypotheses and their associated classifications (i.e., the phylogenetic hypothesis based on the present study compared with those following previous classifications as outlined in Fig. 1), we used Bayesian inference. To test whether one phylogenetic hypothesis is strongly preferred over an alternative phylogenetic hypothesis, we estimated the marginal likelihoods of the different hypotheses, i.e., the models M_0 , M_1 , etc., using the stepping stone sampling approach (Xie et al., 2011) implemented in MrBayes, version 3.2.1 (Ronquist et al., 2012). For each model, we used an informed prior (i.e., monophyly constraints), following the “preferred” strategy of Bergsten et al. (2013). Thus, for each hypothesis we defined hard constraints for all major clades (see Fig. 2). For the stepping stone approach we set the number of generations to 7,500,000, the alpha-shape parameter to 0.3 – a value within the range Xie et al. (2011) found optimal –, the sampling frequency to 500, nsteps to 50, and the default for the burn-in (i.e., there are 147,000 generations per step). Convergence was assessed based on the standard deviation of split frequencies. According to Kass and Raftery (1995), there is strong support for a phylogenetic hypothesis if the 2ln Bayes factor ($2\ln B_{10}$) – resulting from the difference between the marginal likelihoods of both hypotheses – is > 10 .

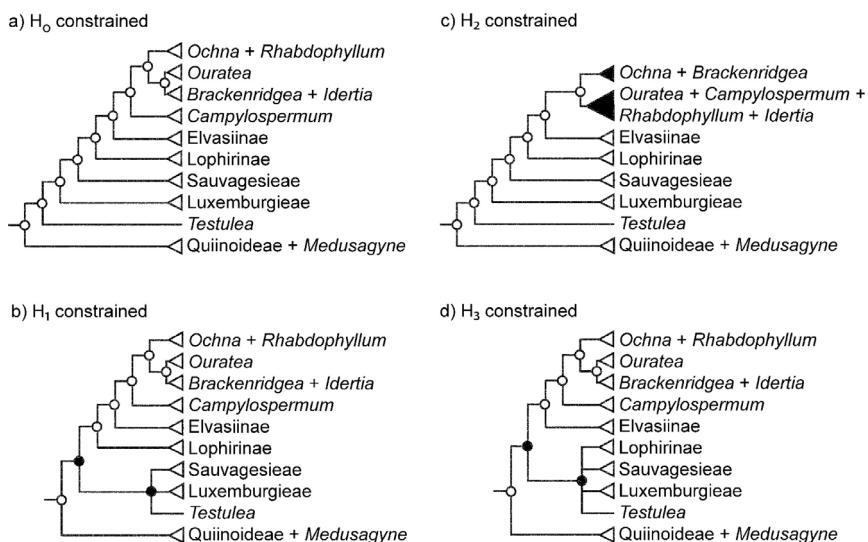

Figure 2. Phylogenetic hypotheses used for Bayesian hypothesis testing. The null hypothesis H_0 , which corresponds to the phylogeny obtained in the present study, is compared to three alternative phylogenetic hypotheses (H_1 - H_3) that represent assumptions about phylogenetic relationships from previous classifications of Ochnaceae. Monophyly constraints are defined for all major clades (open circles and triangles). Solid circles and triangles indicate different constraints compared to H_0 .

4.2.6 Ancestral state reconstruction

Eight morphological characters, which identify major groups of Ochnaceae in premolecular classifications, were selected for the reconstruction of their evolution. Characters were scored for all taxa included in the molecular phylogeny following Amaral (1991) and Amaral & Bittrich (in press) for Ochnaceae s.str, Schneider and Zizka (in press) for Quiinaceae, and Dickison (1990) for *Medusagyne*. Two characters, carpel number and anther dehiscence, partially show considerable intrageneric variability. To reflect that variability (which is not fully covered by the taxon sampling), all congeners were assigned a genus-level score which covers the range of character states. All characters are binary or multistate (for character states of terminals see Table S1 and Fig. 4).

Ancestral state reconstructions were performed using BayesTraits, version 2.0 (beta) (Pagel et al., 2004; Pagel & Meade, 2006). Pooled trees from independent runs of Bayesian analysis (see above) were loaded in Mesquite, version 2.75 (Maddison and Maddison, 2011) specifying a burn-in fraction of 0.25, as in the Bayesian analysis above. Trees were rooted with the outgroup taxa using the “Root tree with selected taxa as outgroup” option of the Alter/Transform module. Subsequently, the outgroups were pruned and a subsample of 1000 post-burnin trees produced with the option “sample trees from separate NEXUS file”. Based on the Bayesian consensus tree, well-supported nodes of the major taxonomic lineages were selected for ancestral state reconstruction. The command lines for the specified nodes as required by the addMRCA command in BayesTraits were generated with the program BayesTrees, version 1.3 (Meade and Pagel, 2011). Ancestral state reconstructions were performed for each character separately using the module MultiState as implemented in BayesTraits (Pagel et al., 2004; Pagel and Meade, 2006) and the sample of 1000 post-burnin trees. Initially, a maximum likelihood analysis was run to derive an empirical prior. Preliminary Bayesian analyses were run with a reverse jump Markov chain Monte Carlo approach, an exponential hyperprior with its mean seeded from a uniform distribution of 0-20, 10×10^6 generations, sampling every 1,000th generation, discarding the first 2,500,000 iterations as burnin, and varying RateDev parameters until acceptance rates reached values of 20 to 40% to ensure adequate mixing. Finally, ancestral states were reconstructed for the selected nodes with the adjusted RateDev parameter and the same settings as before but running the analysis for 50×10^6 generations and sampling every 10,000th generation. Three independent runs were performed to check for stationarity of the harmonic means. If probability values for a given state were < 0.70 , alternative states were tested using the fossil command in BayesTraits and calculating the Bayes factor (BF) as described in the programs manual. A BF of two to five indicates positive, and a BF of greater than five indicates strong support.

4.3 Results

4.3.1 Sequences/matrices

Our concatenated data set contained 3932 nucleotide sites after the exclusion of ambiguous characters. All 63 ITS and 69 *matK*, 49 *ndhF*, 75 *rbcL*, and 72 *trnL-F* sequences were newly obtained for this study. For 33 taxa all five gene regions were successfully sequenced, for 28 taxa only four regions, for 15 taxa three regions, for four taxa two regions, and for two taxa only one region could be obtained (in some cases only partially). Important characteristics of the sequences and the alignment are summarized in Table 3.

Table 3. Alignment characteristics according to region.

	ITS	<i>matK</i>	<i>ndhF</i>	<i>rbcL</i>	<i>trnL-F</i>
Alignment length	626	1315	858	552	1048
#characters excluded	273	21	--	--	173
#variable characters	135	517	250	80	333
#constant characters	218	777	608	472	542

4.3.2 Phylogenetics of Ochnaceae s.l.

Maximum likelihood and Bayesian analyses of the combined data produced largely congruent trees and contained no well-supported incongruences. The names of suprageneric taxa used in this section follow the new classification presented here (see discussion). Ochnaceae were maximally supported as monophyletic (100% BS, 1.0 PP), and Ochnoideae were inferred as sister to a clade of Medusagynoideae and Quiinoideae, though with only weak support (Fig. 3). *Testulea* emerged as sister to the rest of Ochnoideae (100% BS, 1.0 PP). Within Quiinoideae all nodes received maximum support: *Froesia* Pires is sister to the rest of Quiinoideae, and *Quiina* Aubl. is sister to a clade of *Touroulia* Aubl. and *Lacunaria* Ducke. The clade of *Luxemburgia*/*Philacra* (99% BS, 1.0 PP) formed the sister clade to the remaining genera of Ochnoideae (100% BS, 1.0 PP). The clades of tribes Sauvagesieae (96%, 1.0 PP) and Ochneae (100% BS, 1.0 PP) – the former Sauvagesioideae *pro parte* and Ochnoideae – are monophyletic and sister to each other (96% BS, 1.0 PP). Within Sauvagesieae, *Blastemanthus* is sister to the rest of this tribe (with low support), and a clade uniting *Cespedesia* Goudot, *Godoya* Ruiz & Pav., *Krukoviella* A.C. Sm. and *Rhytidanthera* Tiegh. is sister to the remaining genera, although with weak support. *Wallacea* Spruce ex Benth. & Hook.f./*Poecilandra* Tul. are sister to a clade comprising *Adenarake* Maguire & Wurdack, *Euthemis* Jack, *Sauvagesia*, *Schuurmansi* Blume, *Schuurmansiella* Hallier f., and *Tyleria* Gleason (100% BS, 1.0 PP). *Sauvagesia* is polyphyletic when including the Old World species *Sauvagesia serrata* (Korth.) Sastre, as this species is sister to a clade consisting of *Adenarake*, the New World species of *Sauvagesia*, and the clade of *Euthemis*, *Schuurmansi*, *Schuurmansiella*, and *Tyleria*. The clade of *Euthemis* and *Schuurmansiella* is sister to *Schuurmansi*, but

their relationships are poorly supported. Within Ochnaceae, *Lophira* and *Elvasia* DC. are strongly supported as subsequent sister lineages to the clade composed of the remaining genera (100% BS, 1.0 PP) as is *Elvasia* to the remaining genera of the tribe (96% BS, 1.0 PP). The relationships within Ochninae are less clear due to low support values, although the analyses infer each of the genera as monophyletic.

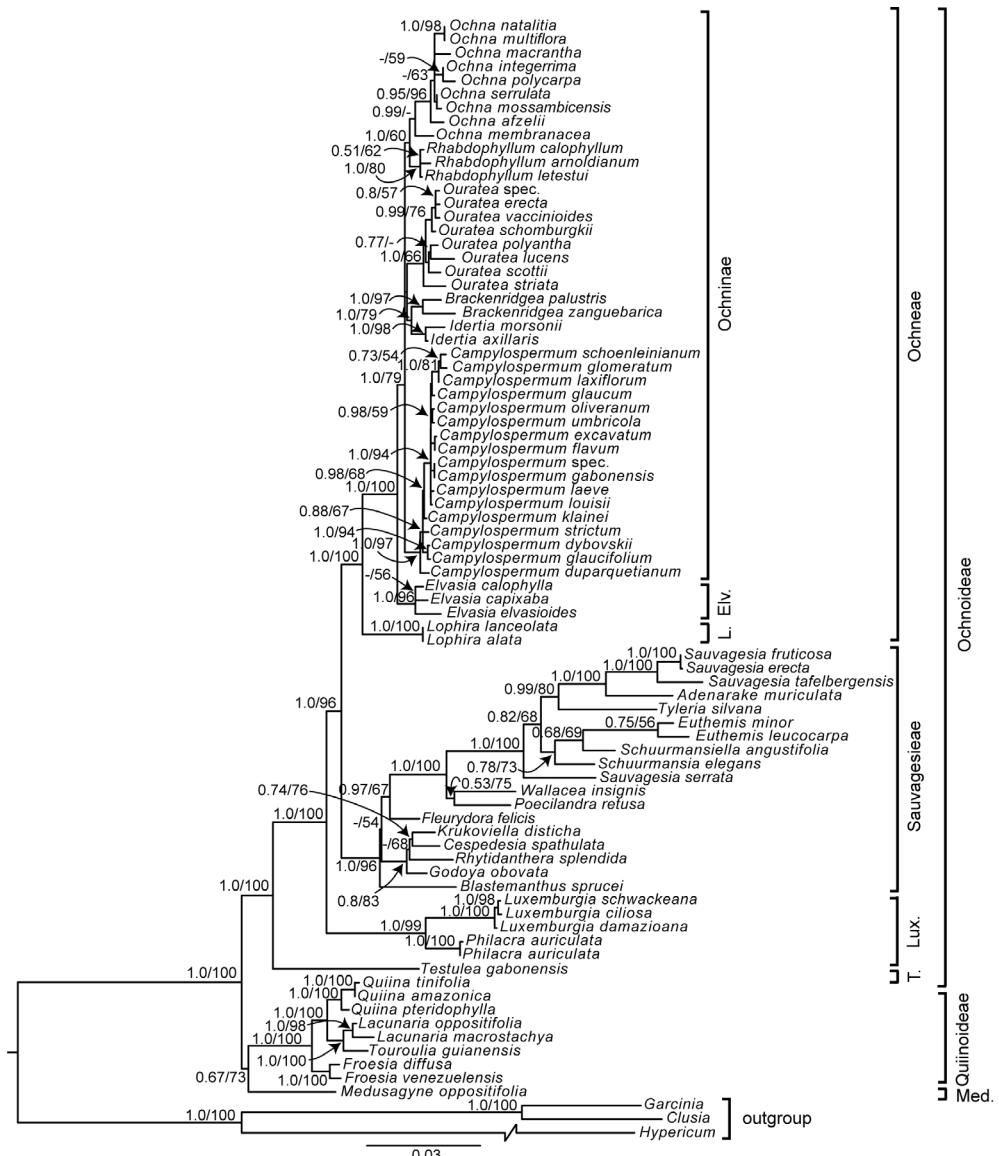

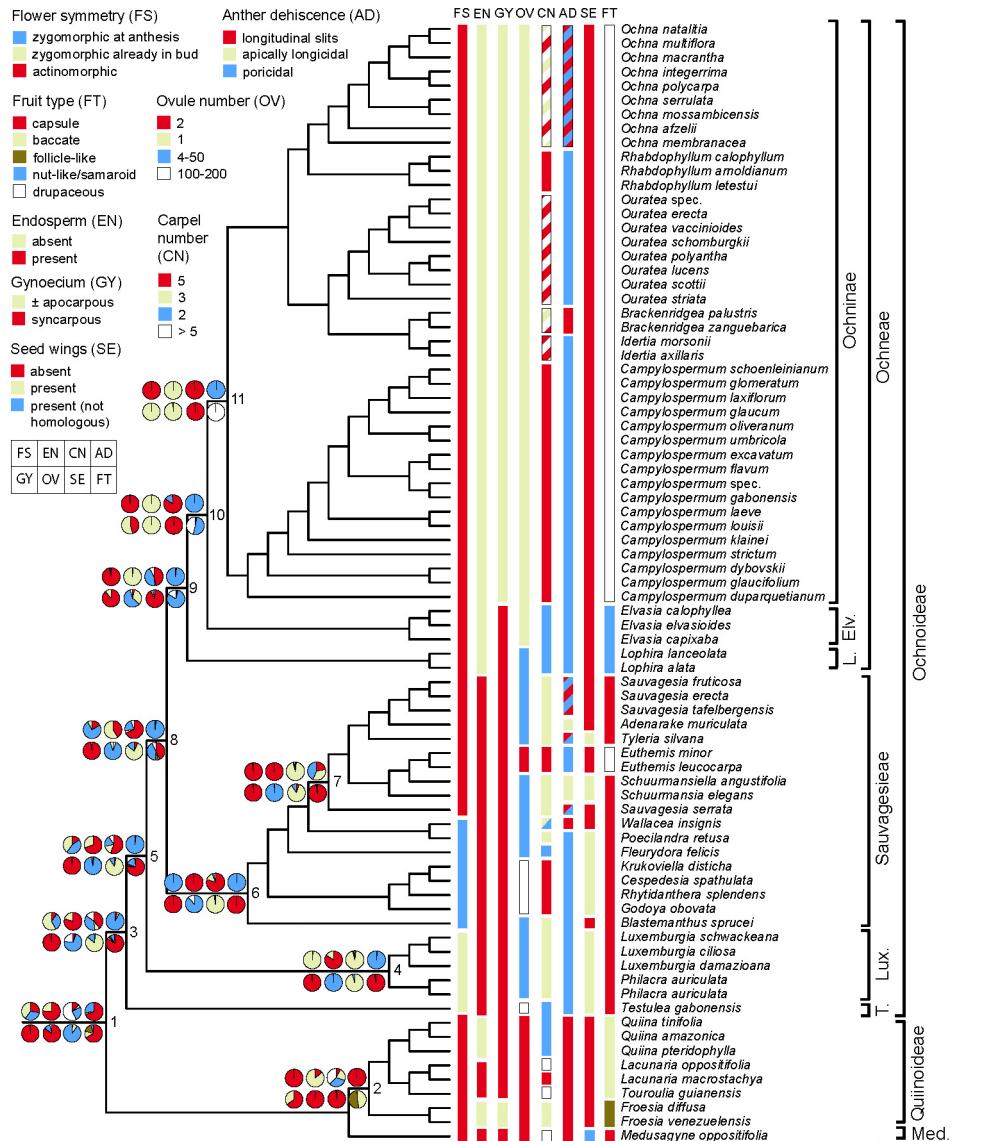

Figure 3. Maximum likelihood tree of Ochnaceae s.l. based on the combined DNA regions with posterior probabilities obtained from Bayesian Inference and bootstrap support from RAxML analysis (only values ≥ 0.5 [PP] or 50% [BS] are shown). The ranks and suprageneric names are according to the new classification presented here; Ochnaceae, Medusagynaceae and Quiinaceae are accepted at the rank of subfamily, in accordance with APG III (2009). Elv. = Elvsiinae; L. = Lophirinae; Lux. = Luxemburgieae; Med. = Medusagynoideae; T. = Testuleeae.

p.249

Figure 4. Ancestral state reconstructions for eight taxonomically important morphological characters of well-supported major clades of Ochnaceae. The proportions of the posterior probabilities (see also Table S2) are displayed as pie charts (for arrangement of characters see the rectangular scheme). Character scores are color-coded. To represent intrageneric variability in carpel number and anther dehiscence, all congeners were assigned a genus-level score which covers the range of the character states (see bars with mixed colors; including states not covered by the taxon sampling of the phylogeny). For the classification, see Fig. 3 (outgroups not shown).

Maximum likelihood analyses of each of the five regions separately (topologies not shown) did not show significant differences compared to the analysis of the combined

data with the exception that *Idertia* changed the position with *Elvasia* as sister to the rest of Ochneae (without *Lophira*; 100% BS) in the *trnL-F* tree.

4.3.3 Hypothesis testing

A comparison of the marginal likelihoods obtained from the stepping stone approach revealed that the null hypothesis (H_0 ; see Fig. 2), which corresponds to the tree obtained from Bayesian inference, is strongly preferred over each of the alternative phylogenetic hypotheses H_1-H_3 . The mean log likelihood of H_0 was -20436.85 , whereas H_1 (enforcing a clade of Sauvagesieae, *Testulea*, *Luxemburgia* and *Philacra*) received a log likelihood of -20532.21 . The hypothesis H_2 , enforcing Ochninae (*Brackenridgea*, *Ochna*) and Ourateinae (*Campylospermum*, *Idertia*, *Ouratea*, *Rhabdophyllum*) as circumscribed in previous classifications to be monophyletic, received a log likelihood of -20452.31 . The log likelihood for the hypothesis (H_3) enforcing *Lophira* to be included in a clade of Sauvagesieae, *Testulea*, *Luxemburgia* and *Philacra* was -20557.48 . Thus, the Bayes factors ($2\ln B_{10}$) for the comparisons between H_0 with each of the alternative hypotheses are > 10 .

p.250

4.3.4 Ancestral state reconstruction

Character state reconstructions showed that zygomorphic flowers are ancestral and actinomorphic flowers derived in Ochnoideae, with the presence of zygomorphy already at early stages of flower development receiving higher PP compared to zygomorphy that develops only at anthesis (Fig. 4, node 3; PP 0.57 [BF 3.0] versus 0.33; see also Table S2). Actinomorphic flowers arose independently in Ochneae (node 9, PP 0.97) and the clade uniting *Sauvagesia* s.l. and related genera (node 7, PP 0.98). The lack of endosperm is probably ancestral in Quiinoideae (node 2, PP 0.86), but derived in Ochnoideae (node 3, PP 0.8). A syncarpous gynoecium is ancestral in Ochnaceae (node 1, PP 0.99), and it was most likely present in the most recent common ancestors (MRCA) of Quiinoideae (node 2, PP 0.66, BF 5.8) and Ochnoideae (node 3, PP 0.98) too. A near-apocarpous gynoecium evolved twice, once in Quiinoideae (*Froesia*) and once in Ochnineae. Ovule numbers of 4-50 are probably the ancestral condition in Ochnoideae (node 3, PP 0.71), whereas two ovules per carpel is ancestral for Ochnaceae (node 1, PP 0.85). A single ovule per carpel is a derived state that emerged early in the evolution of Ochneae, somewhere along the branch of Elvasiinae + Ochninae (nodes 9-10). The evolution of carpel number along the backbone of Ochnaceae is unclear due to the lack of strong support for single states. However, two or five carpels is inferred as the ancestral condition in Ochnoideae (e.g. nodes 3, 5, 8), whereas three carpels is ancestral in *Sauvagesia* s.l. and related taxa (node 7, PP 0.95). For Quiinoideae (node 2), the ancestral condition remains undetermined. Anther dehiscence was poricidal in the MRCA of Ochnoideae (node 3, PP 0.91) and in all other major clades of that subfamily. Only in *Sauvagesia* s.l. and related

taxa (node 7), the ancestral state is unclear. Therefore, dehiscence by longitudinal slits, either over most of the length of the anther or confined to the apical zone, is a derived state in Ochnoideae. Septicidal capsules are ancestral in Ochnaceae (node 1, PP 0.67, BF 1.54) and Ochnoideae (node 3, PP 0.84). Nut-like to samaroid fruits are the ancestral condition in Ochneae (node 9, PP 0.80). Seeds with wings is probably ancestral in Ochnoideae (node 3, PP 0.84). In contrast, the loss of wings in the MRCA of Ochneae is well supported (node 9, PP 0.92). In Sauvagesieae the loss of wings is also derived.

4.4 Discussion

4.4.1 Relationships and circumscription of Ochnaceae

Molecular phylogenetics revealed that Medusagynaceae, Ochnaceae, and Quiinaceae form a well-supported clade within Malpighiales, but relationships between all three have long been unclear due to the lack of support in earlier molecular phylogenetic studies (Fay et al., 1997; Savolainen et al., 2000; Davis and Chase, 2004). This phylogenetic uncertainty together with the opportunity to eliminate a monogeneric family Medusagynaceae led APG III (APG, 2009) to unite the three families, forming a broadly defined Ochnaceae. In contrast, in some more recent studies all three families are kept separate because they form distinct clades that are also morphologically well characterized (Wurdack and Davis, 2009, Matthews et al., 2012; Xi et al., 2012; Endress et al., 2013). As inferred from a phylogenomic study, Ochnaceae are sister to a clade of Medusagynaceae and Quiinaceae (Xi et al., 2012). In the present study, which is based on the most complete taxon sampling of Ochnaceae to date, the relationships between the three families remain poorly supported, but each family forms a well-supported clade.

There are several potential synapomorphies in support of a broadly defined Ochnaceae including, for example, nectarless flowers, sepals often being of different size within flowers and with more than three vascular traces, petals reflexed over the sepals and directed toward the pedicel, anthers basifixated or almost basifixated, and the presence of a short gynophore (Matthews et al., 2012; Endress et al., 2013). However, the families in the narrow sense are also morphologically well characterized by a set of potential apomorphies. Ochnaceae s.str. share adaptations to buzz-pollination with poricidal anthers, the stamen filaments with an abruptly narrow attachment zone of the anthers, and a crystal layer in the endostesta (Amaral, 1991; Matthews et al., 2012). The alternate phyllotaxis and the often fimbriate or intrapetiolarly fused stipules also distinguish them from Medusagynaceae and Quiinaceae; phyllotaxis is opposite or whorled in the last two families and stipules are interpetiolar (Quiinaceae) or absent (Medusagynaceae). The formation of morphologically and/or functionally unisexual flowers characterizes Medusagynaceae and Quiinaceae (only lacking in *Froesia*), whereas in Ochnaceae,

this is restricted to *Euthemis*, *Schuurmansi*, and *Schuurmansiella* in Sauvagesioideae (Kanis, 1968; Amaral, 1991). Potential apomorphies of Quiinaceae are a floral cup, a conspicuously ribbed ovary at anthesis with the ribs being not transversally subdivided, but vascularized, and in each locule there are two superimposed (collateral in *Froesia*) ovules that face in the same direction (Matthews et al., 2012), whereas in Medusagynaceae there are also two superimposed ovules in each locule but the micropyles of the ovules are directed towards each other, and the ovary ribs are transversally subdivided, but not vascularized.

Leaf venation is an important character that unites Medusagynaceae, Ochnaceae and Quiinaceae (e.g., Hickey and Wolfe, 1975), but it also distinguishes Quiinaceae from the other two. In both Quiinaceae and Ochnaceae there is a tendency for parallel and densely spaced secondary and/or tertiary veins. However, the extremely dense and parallel tertiary veins of Quiinaceae that are perpendicular to the secondary veins are unique and also a potential apomorphy (Schneider et al., 2002, 2006). Shared features of a clade uniting Medusagynaceae and Quiinaceae are, for example, extreme polystemony, a massive thecal septum that persists after anther dehiscence, styles radiating outward from the ovary, two lateral superimposed ovules per carpel, and conspicuous lateral ribs on the ovary wall at anthesis (Matthews et al., 2012). Vestured pits, which have been supposed to contain a strong phylogenetic signal (Jansen et al., 2001), may be a synapomorphy of Ochnaceae s.l.: they characterize Ochnaceae (except *Sauvagesia*) and Medusagynaceae (Jansen et al., 2001), and Gottwald and Parameswaran (1967) also reported them for Quiinaceae, but Jansen et al. (2001) could not confirm their presence in that family.

In summary, there are good arguments from anatomy, morphology and molecular phylogenetics for both a narrow as well as a broad circumscription of Ochnaceae. Which one to choose is therefore a rather subjective decision. However, there are some additional points to consider. First, because stability of classifications is desirable (Godfray and Knapp, 2004) and because APG III (2009), with a broadly defined Ochnaceae, is now widely accepted and adapted in recent flora works, classifications and databases (e.g., Fiaschi et al., 2010; Stevens, 2001 onwards; Tropicos, 2013), keeping Ochnaceae s.l. is preferable. Second, elimination of monogeneric families is also a desirable goal of modern classifications (e.g., APG III, 2009). Here, the question is whether the monogeneric Medusagynaceae are sufficiently distinct from the other two families to merit recognition at family rank as, for example, Platanaceae are (see APG III, 2009). Medusagynaceae is a widely-used name, supported by numerous potential apomorphies, and easily distinguished from Ochnaceae and Quiinaceae. Nonetheless, compared to Platanaceae, distinction of Medusagynaceae is not strong. Thus, given the basic similarity of the three families with numerous potential synapomorphies for the Ochnaceae s.l. clade and the arguments outlined above, we agree with the classification of APG III (2009) in merging all three families. To avoid confusion, however, we suggest

that Ochnaceae s.l. should be used for the broader circumscription until this use has become widely established.

4.4.2 Infrafamilial relationships and classification

Accepting a broadly defined Ochnaceae has immediate consequences for infrafamilial classification. Because Medusagynaceae and Quiinaceae are recognized at the rank of subfamily, infrafamilial names of previous classifications of Ochnaceae have to be accommodated accordingly. For example, subfamily Ochnoideae sensu Amaral (1991) will here be recognized at the rank of tribe. Thus, Ochneae and Sauvagesieae correspond to the Sauvagesioideae and Ochnoideae of pre-molecular classifications and to Engler's (1874) "Exalbuminosae" and "Albuminosae".

The separation into infrafamilial groups based on the absence (= Ochneae; Exalbuminosae) or presence of endosperm (= Sauvagesieae; Albuminosae) as suggested by Engler (1874) finds partial support in the monophyletic Ochneae in the present analysis. However, Sauvagesieae in their traditional circumscription (including *Testulea*, *Luxemburgia*, and *Philacra*) are paraphyletic because *Testulea* is the sister group of the rest of Ochnoideae and a clade with *Luxemburgia* and *Philacra* is the next sister group to the rest of the subfamily (Fig. 3). Therefore, it is necessary to elevate *Testulea* and *Luxemburgia + Philacra* to tribal rank. There are morphological characters (probably apomorphic) supporting tribes Luxemburgieae and Testuleeae: *Testulea* differs from the rest of Ochnoideae in having tetramerous flowers with only one bracteole, a single fertile stamen and the staminodes fused into a column up to two thirds of their length, besides leaves with brochidodromous venation; *Luxemburgia* and *Philacra* differ in flowers that are obliquely zygomorphic already in bud with the stamens surrounding the ovary only adaxially and filaments that are basally or completely fused. Thus, in our new classification Ochnoideae (former Ochnaceae s.str.) contain tribes Ochneae, Sauvagesieae, Luxemburgieae and Testuleeae.

The fact that Sauvagesioideae sensu Amaral (1991; including *Testulea*, *Luxemburgia* and *Philacra*) is not monophyletic is unexpected and it would hardly be inferred by the analysis of morphological characters alone, as both the former subfamilies Ochnoideae (Ochneae in the new classification) and Sauvagesioideae were apparently supported by synapomorphies (Amaral, 1991). The synapomorphies for Ochnoideae (now Ochneae) are the indehiscent fruits, ovules with united integuments for most of their length or completely so (see Matthews et al. 2012), and seeds with a strongly simplified testa and without endosperm. On the other hand, the supposed synapomorphies for the former Sauvagesioideae were zygomorphic flowers (with reference to the androecium at least), seeds with wings formed by the exotesta, and the presence of a crystal layer in the endotesta. An explanation for the unexpected result of a paraphyletic Sauvagesioideae may be found by re-evaluating the synapomorphies.

The fruits of *Medusagyne* and the clusioid clade as circumscribed in Xi et al. (2012) open, when dehiscent, along the septal radius (Stevens, 2001 onwards). The presence of septicidal capsules that occur in Testuleeae, Luxemburgieae and Sauvagesieae (with the exception of *Euthemis*) is therefore probably a symplesiomorphic character. On the other hand, the winged seeds and the presence of a crystal layer in the endotesta might be apomorphic characters by comparison with the outgroups (but see below). The seeds of Quiinoideae are wingless, and the wings of the seeds of *Medusagyne* are probably not homologous to those of Testuleeae, Luxemburgieae and Sauvagesieae, because they include a chalazal vascular bundle and have several cell layers (Dickison, 1990; Amaral, pers. obs.).

The presence of winged seeds and the crystalliferous endotesta is correlated with the capsular fruits that occur in the current tribes Testuleeae, Luxemburgieae and Sauvagesieae. Only in *Wallacea* and *Blastemanthus* both the wings and the crystalliferous layer are reduced and their relatively large seeds are water-dispersed in riverine environments in the Amazon region. In other genera of Sauvagesieae with wingless seeds (e.g., *Indosinia*, *Adenarake*, *Sauvagesia* s.l.) the crystalliferous layer is present, even in the genus *Euthemis* with its indehiscent, drupaceous fruits. Indehiscent fruits occur in all genera belonging to tribe Ochnaeae and this, accompanied by the more or less complete fusion of the integuments, apparently led to a simplification of the seed coat including the reduction of the seed wings and crystal layer. Another character that, according to Amaral (1991), could be synapomorphic for former Sauvagesioideae is the presence of zygomorphic flowers. However, the zygomorphy arises in different ways: the flowers of *Testulea* and *Luxemburgia* + *Philacra* are zygomorphic already in the floral bud as the stamen and staminodes (in *Testulea*) or the stamens (in *Luxemburgia* + *Philacra*) are situated at the adaxial side of the flower (in *Luxemburgia* the stamen primordia are already asymmetrically arranged at the early stages of the flower development; Amaral and Bittrich, 1998). In the early branching genera of Sauvagesieae the development of the zygomorphy occurs only during the anthesis with the stamens shifting to the adaxial and the gynoecium to the abaxial region of the flower. If zygomorphic flowers are ancestral in Ochnoideae as now recognized, actinomorphic flowers arose twice in the subfamily: in subtribe Ochninae and in *Sauvagesia* and related genera of Sauvagesieae, many of them with petaloid staminodes around or enveloping the fertile stamens and gynoecium. Additionally, the flowers becoming zygomorphic by shifting stamens and gynoecium only during the anthesis are also derived.

Thus, most of the supposed synapomorphies for the former subfamily Sauvagesioideae, uniting *Testulea*, *Luxemburgia* + *Philacra* and the genera that now belong to Sauvagesieae, are probably synapomorphies for the whole subfamily Ochnoideae (as now recognized) as is largely confirmed by the ancestral state reconstructions.

Quiinoideae (former Quiinaceae) are not subdivided further (Schneider and Zizka, in press). They form a well supported monophyletic group as in previous studies (Schneider et al., 2002, 2006). *Froesia* is sister to the rest of Quiinaceae, as observed in former studies (Schneider et al., 2002, 2006), but the clade of *Lacunaria* and *Touroulia*, sister to *Quiina*, has not been retrieved previously. *Lacunaria* and *Touroulia* share a similar leaf venation pattern, petals with three vascular traces, a polymerous gynoecium with (4-)5-16 carpels (3 in *Froesia*, 2[-5] in *Quiina*), a deep ovary roof, a distinctive epidermis with radially elongate, potentially secretory cells in the furrows between the ovary ribs, and a synascidiate placental zone (Zizka and Schneider, 1999; Schneider et al., 2002, 2006; Matthews et al., 2012; Schneider and Zizka, 2012), most of them being potential synapomorphies.

4.4.3 Relationships below the rank of tribe

Ochneae (former Ochnoideae) are a rather homogeneous group and the circumscription has been clear for a long time with the exception of the odd genus *Lophira*, which was included in Ochnaceae for the first time by Gilg (1893a, 1893b). This genus shares the non-distichous leaves and a two-carpelled, one-celled, many-ovuled ovary with Sauvagesieae (former Sauvagesioideae), whereas the lack of endosperm and unitegmic ovules agree with Ochneae. Here, the molecular data strongly support its inclusion in Ochneae, which in turn also corroborate the taxonomic importance of the endosperm character. Furthermore, the arguments used by Kanis (1968) for its inclusion in Sauvagesioideae (here Sauvagesieae) are weak because a two-carpelled ovary is not an exclusive feature of Sauvagesioideae/Sauvagesieae (see below) and the phyllotaxis is taxonomically problematic (Amaral, 1991). In the morphology-based cladistic analysis of Amaral (1991) without character weighting, *Lophira* formed a clade with *Elvasia* and *Perissocarpa*. However, such a relationship is most likely an artifact caused by homoplastic characters because after downweighting these characters (using the “weighting procedure” suggested by Farris, 1969) *Lophira* emerged as sister to the rest of the subfamily (Amaral, 1991). Although its inclusion in Ochneae is well-supported, the odd gynoecium as described above and the fruit with the outer two sepals being extremely accrescent, wing-forming (the outermost sepal increasing by a factor 10-12, attaining a length of up to 13 cm) clearly separate *Lophira* from the rest of the tribe. Therefore, it seems appropriate to recognize subtribe Lophirinae, following Gilg (1893a), who was the first to suggest its formal separation from the remaining genera.

Besides former Ochneae (here Ochninae) and Lophireae (here Lophirinae), many of those who studied the family also recognized a third tribe, Elvasieae, within Ochnoideae (Engler, 1874; Gilg, 1893a; Dwyer, 1943; Kanis, 1968; Sastre and Lescure, 1978). Elvasieae were monotypic until Steyermark and Maguire (Steyermark, 1984) segregated the new genus *Perissocarpa*. Both are morphologically similar (Wallnöfer, 1998) and

differ from the rest of the family in a 2(-7)-celled ovary with a single ovule per cell and a globose, thin-walled, usually one-seeded indehiscent fruit that in *Elvasia* often possesses aerenchyma. In the present study, *Elvasia* (*Perissocarpa* was not included) is sister to the rest of Ochnaeae (without *Lophira*). Thus, combining morphological and molecular evidence and applying our criteria for recognizing subtribe Lophirinae, *Elvasia* and *Perissocarpa* are segregated as subtribe Elvasiinae.

The rest of Ochnaeae, namely Ochninae (= Ourateeae sensu Engler, 1874; Farron, 1963), are monophyletic in the present study and differ from the remaining tribes by a five-parted perianth, gynobasic styles, almost free carpels that are postgenitally fused, and an accrescent and usually red receptacle that bears one to several black drupelets. Several authors proposed a further subdivision of former Ochnaeae – which correspond to our Ochninae – into subtribes Ochninae and Ourateinae (Farron, 1963, 1985; Kanis, 1968; Sastre, 1988; Sosef, 2008), the first comprising *Ochna* and *Brackenridgea*, the second *Campylospermum*, *Idertia*, *Ouratea* and *Rhabdophyllum*. *Ouratea* is clearly distinct from the rest in having free stipules, straight cotyledons, and generally caducous sepals (Sastre, 1988; Sosef, 2008). Additionally, it is the only Neotropical genus. The African genera of Ourateinae sensu Kanis (1968) all have stipules that are intrapetiolarily fused at the base, persistent sepals and curved cotyledons; *Idertia* is an exception in having straight cotyledons. All four genera of Ourateinae have 10 sessile to shortly stalked stamens with poricidal anthers. In contrast, the two genera of Ochninae generally have more than 10 stamens, and the anthers open by longitudinal slits or pores, but with the filaments well developed, attaining a length of at least one third the length of the anther. Sosef (2008), based on Farron's (1963) and his own observations, suggested that *Ouratea* and *Idertia* are the “basal” genera of Ourateinae, whereas *Rhabdophyllum* is nested in an paraphyletic *Campylospermum*. Although there are good morphological characters supporting the relationships outlined above, our molecular data do not support such relationships or classification. Here, *Campylospermum* is sister to the rest of Ochnaeae, *Brackenridgea* forms a clade with *Idertia*, and *Ochna* with *Rhabdophyllum*. This also contradicts the assumption that *Brackenridgea* is closely related to or even congeneric with *Gomphia* (=*Ouratea*) (van Tieghem, 1902; Ridley, 1922). However, several of the intergeneric relationships of Ochninae as circumscribed here require corroboration by additional data because the branch support, especially in the Maximum Likelihood analysis, is rather low. Additionally, the short branches suggest a rather recent diversification of the whole clade. For these reasons we decided not to recognize formal groups within subtribe Ochninae.

Sauvagesioideae in their traditional circumscription were generally subdivided into tribes Sauvagesieae (=Luxemburgieae sensu Gilg, 1893a) and the monogeneric Euthemideae (Kanis, 1968; Sastre, 1987). However, a segregation of *Euthemis* as a subtribe in our classification lacks support from morphological (Amaral, 1991) or molecular data (this

study), because *Euthemis* is embedded within Sauvagesieae. In the present study, *Euthemis* groups with *Schuurmansiella*, *Schuurmansia*, *Tyleria*, *Adenarake* and *Sauvagesia*. Thus, the five-carpelled, five-locular ovary and the baccate fruit with five usually one-seeded pyrenes that distinguish *Euthemis* from the rest are derived (autapomorphic) characters and there is no reason to infer a sister group relationship to the rest of Sauvagesieae. The grouping of *Euthemis* with *Schuurmansiella* and *Schuurmansia*, the only strictly SE Asian genera of Sauvagesieae, points to a common origin of that clade in this region. The pantropical *Sauvagesia* is the only other member of this subfamily with SE-Asian representatives, but it is polyphyletic according to our molecular data because the Asian *S. serrata* is sister to a clade composed by *Adenarake*, the rest of *Sauvagesia* spp., and three other genera. *Sauvagesia serrata* has been considered to represent a separate monotypic genus – *Neckia* – by Kanis (1968) and predecessors. Sastre (1970, 1971) included *Neckia*, the Neotropical genera *Lavradia* Vell. ex Vand., *Leitgebia* Eichler, *Pentaspatella* Gleason, and *Roraimanthus* Gleason and the African *Vausagesia* Baill. in *Sauvagesia*, considering it – i.e., *S. serrata* – the species with the highest number of putative ancestral characters. Subsequent classifications (Amaral, 1991, 2006) agreed with that of Sastre and also put two other monotypic E- to SE-Asian genera in synonymy of *Sauvagesia* (*Indovethia*, *Sinia*; not included in our molecular study). *Sauvagesia* s.l. (but not including *Adenarake*) is in many characters polymorphic, but has persistent stipules (deciduous in *S. nudicaulis* Maguire & Wurdack) with long marginal cilia, globose or ovoid seeds without wings, and the testa has a conspicuous pattern of flattened hexagonal cells. Now, with the phylogenetic relationships at hand, a critical revision of the broadly circumscribed *Sauvagesia* as established by Sastre (1971) and Amaral (1991, 2006) seems to be highly desirable.

A clade uniting *Cespedesia*, *Godoya*, *Krukoviella* and *Rhytidanthera* was also found in the morphological cladistic analysis of Amaral (1991; as sister group of *Testulea*). All of them are Neotropical and characterized by a scalariform tertiary leaf venation, long stipules that leave an elongate scar, five carpels, high numbers of ovules, sessile stigmas, a capsular fruit that dehisces from the base upwards, and long-winged seeds. *Godoya* and *Rhytidanthera* additionally share the unique club-shaped trichomes at the sepals. *Cespedesia* and *Krukoviella* both have comparatively short sepals, which from an early stage of flower development do not envelop the flower bud. All four genera were part of tribe Luxemburgiinae of Kanis (1968) and Sastre (1987), but in the present study Luxemburgieae form a different clade, only comprising the genera *Luxemburgia* and *Philacra*.

Our finding of a clade uniting *Poecilandra* and *Wallacea* confirms former phylogenetic hypotheses by Engler (1874) and Amaral (1991). Both genera share retuse to emarginate leaves with closely parallel secondary veins, many leaf traces, and anthers covered with wax crystals. These are potential synapomorphies although they occur in some other genera as well (Amaral 1991).

Some names of tribes and subtribes have yet to be validly published. Therefore, new names and diagnoses are provided below.

Elvasiinae Schneider, subtrib. nov., based on Elvasieae Engl. in Nova Acta Acad. Caes. Leop.-Carol. German. Nat. Cur. 37: 20. 1875. – Type: *Elvasia* DC.

Lophirinae Schneider, subtrib. nov., based on Lophireae Baill., Hist. Pl. 4: 210, 218. 1872. – Type: *Lophira* Banks ex C.F. Gaertn.

Ochninae Kanis ex Schneider, subtrib. nov. – Type: *Ochna* L.

Shrubs or trees; gynoecium almost apocarpous; style gynobasic; receptacle accrescent in fruit, red, bearing usually black drupelets.

Testuleeae Schneider, trib. nov. – Type: *Testulea* Pellegr.

Tree; perianth 4-parted; one fertile stamen, staminodes fused into a column; endosperm present.

4.4.4 Character evolution

Polysymmetric, i.e. actinomorphic, flowers were supposed to be the ancestral condition in angiosperms from which monosymmetry (= zygomorphy) originated several times independently, and reversals from monosymmetric flowers to polysymmetric ones were considered rare (Stebbins, 1974; Cronquist, 1988; Takhtajan, 1991). More recent evidence from molecular phylogenies revealed that shifts between both states occurred in both directions in different lineages and that changes to polysymmetry are much more frequent than assumed earlier. Genetic and developmental factors rather favor transitions to polysymmetry (Donoghue et al., 1998). In asterids, for example, actinomorphic flowers were ancestral and zygomorphy arose several times independently. However, reversals to actinomorphic flowers were also frequent (Donoghue et al., 1998). This corresponds with the ancestral state reconstruction in Ochnaceae. Although the ancestral condition of the family is ambiguous, zygomorphic flowers are ancestral in Ochnoideae and actinomorphic flowers evolved secondarily in Sauvagesieae and Ochneae. These reversals are partially associated with a reduction in flower size (Amaral, 1991), a phenomenon known also from other angiosperm groups (Donoghue et al., 1998). In Ochnoideae two types of monosymmetry are distinguished, one that is present early in flower development and one that arises just at anthesis, a difference that may be due to a different evolutionary age and differential depth of rooting in the genetic system (Endress, 2011). Here, the presence of monosymmetry already early in bud is reconstructed as the state originating earlier in the evolution of Ochnoideae.

Floral monosymmetry is a means of precise positioning of the pollinators on the flower and generally leads to more efficient pollination and pollinator specificity (Sargent, 2004). Thus, zygomorphy might have a selective advantage. Most Ochnoideae, including all monosymmetric taxa except *Wallacea*, possess a specialized pollination system because of their poricidal anthers or poricidal system (see below). The pollinators are pollen-collecting bees capable of vibrational, i.e. buzz, foraging (Kubitzki and Amaral, 1991). However, this adaptation to buzz-pollination is independent of flower symmetry because it is present in actinomorphic and zygomorphic flowers. Nonetheless, the ancestral condition of Ochnoideae was a combination of monosymmetry and specialized pollination system that probably had been advantageous for the nectarless plants (see De Luca and Vallejo-Marín, 2013).

Poricidal anthers are ancestral in Ochnoideae and are widely distributed across the subfamily. In Ochneae, only *Ochna* (partial) and *Brackenridgea* show dehiscence by longitudinal slits. In Sauvagesieae, several genera exhibit dehiscence by longitudinal slits that either extend along the anther or are confined to the apical part. Especially interesting is the case of *Sauvagesia*, in which several species have anthers with longitudinal slits (e.g. former *Lavradia*), but the androecium is completely enveloped by petaloid staminodes that leave only a small apical pore for pollen transmission. In a similar way, the poricidal system is established in *Tyleria* and *Adenarake*: in the first, the staminodes are only basally fused but are stabilized by ventral keels, whereas in the latter, they are free but still constitute a poricidal superstructure (Kubitzki and Amaral, 1991). Thus, although anther opening reversed to longitudinal dehiscence in these taxa, buzz-pollination was maintained through the poricidal system, suggesting that there was a strong selective pressure on keeping this pollination type. Once buzz-pollination is established, plants will hardly be able to escape from this rigid pollination type (Kubitzki and Amaral, 1991).

The great majority of the core eudicots are syncarpous and secondary apocarpous arose only in few clades of rosids (e.g. Rosaceae, Sapindales, Malvales) and asterids (Apocynaceae) (Endress, 2011). Syncarpy is considered a key innovation and its evolutionary success is supposed to be linked with the novel intragynoecial compitum which allows an increased offspring quality and quantity (Armbruster et al., 2002). Inspite of the overall benefits from syncarpy, Ochnaceae reveal two independent reversals to a near-apocarpous gynoecium (see Matthews et al., 2012), one in the MRCA of *Froesia* (Quiinoideae) and one in Ochninae. *Froesia* had long been considered apocarpous (e.g. Schneider and Zizka, 1997) and only recently it was detected that the carpels are united over a short zone at the base (Matthews et al., 2012). Ochninae had long been considered apocarpous too (e.g. Gilg, 1893a; but see Baum, 1951), but are syncarpous at the base of the ovary. In contrast to *Froesia*, in which the free parts remain free, these parts are united postgenitally in Ochninae (Matthews et al., 2012). Both groups

also differ strongly in their gynoecium structure. *Froesia* has three carpels that in fruit resemble a follicle with the fibrous pericarp characteristic of Quiinoideae (Schneider and Zizka, *in press*); it is doubtful, if a compitum is present (Matthews et al., 2012). Ochninae have a short compitum, bulging ovaries, variable carpel numbers (3-15) and carpels that develop into indehiscent drupelets. Inspite of their structural differences, the independent reversal to apocarpy in both lineages might have been facilitated by a predisposition for variable and higher carpel numbers in the family (in Ochnoideae and Quiinoideae; see Fig. 4). According to Endress (2006), it is architecturally more difficult to allow an efficient compitum with more than five carpels. Hence, there is less constraint for carpel position in such multicarpellate gynoecia.

The presence versus absence of endosperm has long been used to subdivide Ochnaceae into subfamilial clades (e.g. Engler, 1874; Amaral, 1991). However, the presence of endosperm was reconstructed as plesiomorphic in Ochnaceae and thus it is not suitable for uniting taxa in Ochnoideae. In contrast, the early absorption of the endosperm is a derived state in Ochneae and confirms Engler's "Exalbuminosae". For Quiinoideae, in turn, the early absorption of endosperm was inferred as the ancestral state. Thus, the reversal to endosperm unites *Touroulia* and *Lacunaria*. The number of ovules varies between one and up to 200. High ovule numbers were reconstructed as the ancestral condition in Ochnoideae, whereas a single ovule is derived and unites Ochninae and Elvasiinae.

Seeds with wings and, thus, wind-dispersal are ancestral in Ochnoideae and Ochnaceae (however, it is unclear if the wings of *Medusagyne* are homologous to those of Ochnoideae). Winged seeds are therefore not suited for grouping the early branching taxa. Within Sauvagesieae, the loss of wings occurred independently in *Blastemanthus*, *Wallacea*, *Euthemis*, and in the clade of *Adenarake* and *Sauvagesia*. The loss of wings in *Blastemanthus* and *Wallacea* is probably related to their occurrence in inundated forests with the fruits being adapted to hydrochory. In *Euthemis*, the loss is coupled with the evolution of indehiscent fruits and the different dispersal mode. The same is true for unwinged seeds of Ochneae.

4.5 Conclusion

Our molecular data provide for the first time a robust phylogenetic framework for the evaluation of previous phylogenetic assumptions and a modern classification of Ochnaceae s.l. Ochnaceae comprise the subfamilies Ochnoideae Burnett, Quiinoideae Luerss., and Medusagynoideae Reveal. The long-standing subdivision of Ochnoideae into Ochneae and Sauvagesieae (=Ochnoideae and Sauvagesioideae in traditional classifications) was basically confirmed, except that the latter is paraphyletic in its traditional circumscription due to the position of *Testulea* as sister to the rest of Ochnaceae. To avoid paraphyly, we segregate here tribes Luxemburgieae (*Luxemburgia*, *Philacra*) and Testuleeae (*Testulea*) and redefine the circumscription of Sauvagesieae. Within the Ochneae, we corroborated the inclusion of *Lophira*, thus recognizing the subtribes Ochninae (*Brackenridgea*, *Campylospermum*, *Idertia*, *Ochna*, *Ouratea*, *Rhabdophyllum*), Elvsiinae (*Elvasia*, *Perissocarpa*), and Lophirinae (*Lophira*). Ochninae comprise all six genera which had formerly been partitioned between Ochninae and Ourateinae, a concept that could not be confirmed in the present study. In contrast to previous classifications, Sauvagesieae (*Adenarake*, *Blastemanthus*, *Cespedesia*, *Euthemis*, *Fleurydora*, *Godoya*, *Indosinia*, *Krukoviella*, *Poecilandra*, *Rhytidanthera*, *Sauvagesia*, *Schuurmansia*, *Schuurmansiella*, *Tyleria*, *Wallacea*) are not further subdivided here. Especially the circumscription of *Sauvagesia* and the unclear subdivision of and relationships within Ochninae require further investigation using additional molecular data and/or a more comprehensive taxon sampling. Ancestral state reconstructions confirmed the taxonomic value of most characters used in previous classification for defining major clades. However, some states previously considered synapomorphic turned out to be plesiomorphic (e.g. zygomorphic flowers for Sauvagesieae). It was shown that zygomorphic flowers, poricidal anthers, a syncarpous gynoecium, numerous ovules, septicidal capsules, and winged seeds with endosperm are the ancestral condition in Ochnoideae. It is noteworthy that although poricidal anthers reversed to longicidal in several lineages, buzz-pollination was maintained by the evolution of poricidal superstructures, indicating a strong selective pressure on keeping that specialized pollination system. Now that a molecular framework is available, we are looking forward to resolving also pending issues such as the timing of the diversification process and the reconstruction of the complex biogeographic history of Ochnaceae.

Abstract

Ochnaceae is a pantropical family in the order Malpighiales. A recently published molecular phylogeny of the Ochnaceae identified three subfamilies, viz. Medusagynoideae, Quiinoideae and Ochnoideae. Clades within the latter were classified at tribal and subtribal level. The palaeotropical genus *Campylospermum* is placed in the tribe Ochneae, subtribe Ochninae, together with the genera *Brackenridgea*, *Idertia*, *Ochna*, *Ouratea*, and *Rhabdophyllum*. We reconstructed the phylogenetic relationships of the family using three chloroplast markers (*matK*, *rbcL*, *trnLF*) with intensified taxon sampling for the Ochninae, so as to focus on the relationships within this subtribe with special emphasis on the genus *Campylospermum*. Our maximum likelihood and Bayesian analyses corroborate the phylogenetic backbone previously recognized while two clades could be distinguished within the genus *Campylospermum*. The first comprises the West/Central African *Campylospermum* species while the second includes the West/Central African *C. elongatum* and all East African and Malagasy species. The latter clade is retrieved as sister to *Idertia* in both analyses. In general, however, phylogenetic relationships within the Ochninae are poorly supported, which points to the need of additional data to further resolve relationships within Ochnaceae in general and Ochninae in particular.

Keywords: Africa, biogeography, *Campylospermum*, chloroplast markers, Madagascar, Ochnaceae, Ochninae, Ochnoideae, phylogeny, rain forest.

5.1 Introduction

Ochnaceae is a family of trees, shrubs or rarely herbs (species of *Sauvagesia* L.) widely distributed in tropical and subtropical forests and savannas of the Old and New World. The family contains about 500 species in 27 genera (Amaral 1991; Amaral and Bittrich 2014). The Neotropics comprise the highest number of species: about 300-350 in 15 genera. In Africa, including Madagascar, 150 species and nine genera occur while the lowest diversity is observed in South-East Asia, hosting 20 species in eight genera (Kanis 1968; Sastre 2003; Verdcourt 2005; Amaral and Bittrich 2014).

Ochnaceae have adaptations for buzz-pollination, notably the long, apically poricidal anthers (Kubitzki and Amaral 1991; Matthews et al. 2012), which also act as a synapomorphy for the Ochnoideae (Schneider et al. 2014). Ochnaceae are characterised by filaments that are abruptly narrowed where they attach to the anthers, the branching of the ovule bundle into the (outer) integument from the raphe (Matthews et al. 2012), and the densely spaced parallel secondary veins and the tertiary veins perpendicular to these (Amaral and Bittrich 2014). Flowers are actinomorphic or zygomorphic, and are basically pentamerous even though the number of sepals, petals and stamens is not constant within the family (Matthews et al. 2012; Amaral and Bittrich 2014). Bayesian ancestral state reconstructions showed that zygomorphic flowers are ancestral in Ochnoideae and actinomorphic flowers evolved secondarily in Sauvagesieae and Ochneae (Schneider et al. 2014). Several genera have winged seeds, which are probably wind-dispersed (Amaral and Bittrich 2014). Winged seeds with endosperm are a synapomorphy of the Ochnoideae and Ochnaceae (Schneider et al. 2014).

Molecular phylogenetic studies within the Malpighiales often recognized the current subfamilies as families, placed the Ochnaceae (now Ochnoideae Burnett) as sister to both the Medusagynaceae (now Medusagynoideae Reveal), a monotypic family from the Seychelles (Dickison 1990; Fay et al. 1997), and Quiinaceae (now Quiinoideae Luerss.), a tropical American family. The three groups form a distinctive clade (Nandi et al. 1998; Savolainen, Chase, et al. 2000; Davis et al. 2005; Schneider et al. 2006; Korotkova et al. 2009; Soltis et al. 2011). Recently, the first comprehensive molecular phylogeny of Ochnaceae was inferred from combined plastid loci (*matK*, *ndhF*, *rbcl*, *trnLF*) and nuclear ribosomal sequences (ITS1, 5.8S, ITS2) (Schneider et al. 2014). This study presented a new subfamilial and tribal classification for the family, directed by the recognition of monophyletic groups. The Ochnoideae were divided into four tribes (Luxemburgieae, Ochneae, Sauvagesieae and Testuleeae), the Ochneae contain three subtribes (Elvasiinae, Lophirinae and Ochninae). Some of the formal and informal pre-molecular classifications before the advent of phylogenetics, for instance those of Engler (1874) and Gilg (1893), recognized a main division of Ochnaceae into the Albuminosae (presence of endosperm) and Exalbuminosae (absence of endosperm). Schneider

et al. (2014), found that the presence of endosperm is a shared derived character for Ochninae, but in the larger context of the family is a homoplasious character.

The subtribe Ochninae (Schneider et al. 2014) is the most species-rich clade of the family. It comprises the genera *Brackenridgea* A.Gray (c. 9 spp.), *Campylospermum* Tiegh. (c. 55 spp.), *Idertia* Farron (1 spp.), *Ochna* L. (c. 80 spp.), *Ouratea* Aubl. (c. 200 spp.) and *Rhabdophyllum* Tiegh. (8 spp.) (chapter 2 and 3). Previous classifications grouped the African genera *Campylospermum*, *Idertia*, *Rhabdophyllum* and the Neotropical genus *Ouratea* into the subtribe Ourateinae while *Brackenridgea* and *Ochna* were grouped into Ochninae, all sensu Kanis (1968). The latter two genera have even been treated as synonyms, for example by Bamps & Farron (1967). While the Ourateinae have ten sessile to shortly stalked stamens with poricidal anthers, the Ochninae generally have more than ten stamens, anthers that open by longitudinal slits or pores, and filaments attaining a length of at least one third the length of the anthers. The phylogeny presented by Schneider et al. (2014) demonstrated that both subtribes as historically delimited are non-monophyletic, and retrieved *Idertia* as sister to *Brackenridgea* with maximum support from Bayesian analyses (Schneider et al. 2014). Species of *Idertia* have cotyledons that are similar in size, straight and accumbent (cotyledons lying edgeways to the radicle), which are regarded as 'primitive' features (Farron 1985) and shares these features with the Neotropical genus *Ouratea*. *Idertia* is also distinct from other African Ochninae by the few, straight secondary nerves and the setose leaf margin (Sosef 2013). Actually, within Ochnaeae, Schneider et al. (2014) retrieve *Campylospermum* as a clade sister to the rest of Ochnaeae while *Rhabdophyllum* forms a clade with *Ochna*.

Species of *Campylospermum* are trees or treelets with various architecture, and have been subject to recent taxonomic revision (Bissiengou et al. 2013). Before that, the genus was taxonomically studied in detail by Farron (1985) who subdivided it into six sections: *Bisetaria* (Tiegh.) Farron, *Cercanthesum* (Tiegh.) Farron, *Campylospermum* Tiegh., *Diphyllodium* (Tiegh.) Farron, *Notocampylum* (Tiegh.) Farron and *Monelasmum* (Tiegh.) Farron. He mainly used characters of the cotyledons and embryo as well as those related to the position of the inflorescence to distinguish between these sections. In the genus *Campylospermum* cotyledons can be either of similar size and incumbent (sections *Notocampylum* and *Diphyllodium*) or accumbent (sections *Campylospermum* and *Cercanthesum*), or dissimilar in size and incumbent (section *Monelasmum*). The monotypic section *Bisetaria* is characterized by unique features of the leaf and stipules. These sectional names were based on genera already established by (Van Tieghem 1902b, d, c). On the basis of the cotyledon characters, Farron (1985) suggested that the more derived species tend to have heterocotyledonous seeds (*Rhabdophyllum*, *Campylospermum* section *Monelasmum*) while the ancestral state would be isocotyledonous. The Malagasy species were not included in this sectional delimitation, which was only restricted to the continental Africa. The cotyledons of

Malagasy species are similar in size and accumbent (Perrier de la Bâthie 1941, 1951), characters corresponding to the sections *Campylospermum* and *Cercanthemum*.

East African or Malagasy *Campylospermum* species are absent in the phylogeny produced by Schneider et al. (2014). Inclusion of these species would be pivotal for explaining their ecological preference for humid forests, similar to that of the West/Central African representatives. During the Eocene African rain forests occupied a continuous surface extending from west to east coast (Burgess et al. 1998; Burgess et al. 2007), which explains the floristic affinities between the East and West/Central African regions (White 1979; Burgess and Clarke 2000), and phylogenetic patterns within *Campylospermum* could corroborate those found in other groups (Lovett and Wasser 1993; Jacobs 2004; Couvreur et al. 2008). Furthermore, the Malagasy species are still in desperate need of a taxonomic revision. The last revisions were those from Perrier de la Bâthie (1941, 1951) and we are almost sure that several undescribed species lie hidden amongst the herbarium collections. But, before someone can embark on a taxonomic revision of the Malagasy *Campylospermum* species, it seems best to first infer the phylogenetic relationships within the subtribe Ochninae, to test whether the genera as delimited at present are monophyletic.

This study presents the phylogeny of Ochnaceae including an intensified sampling within the subtribe Ochninae with special emphasis on the East African and Malagasy species of *Campylospermum*. We aim at:

- (1) conducting a molecular phylogenetic study of the Ochnaceae based on chloroplast markers (*matK*, *rbcL*, *trnLF*) in order to investigate whether the previous phylogeny based on combined chloroplast and nuclear gene regions can be confirmed,
- (2) assessing whether *Campylospermum* is monophyletic, and whether or not the previously proposed sectional subdivision can be corroborated by our phylogeny.

5.2 Materials and Methods

5.2.1 Taxon sampling

Voucher information for all accessions is provided in Table 1. Representatives of all currently recognized subfamilies Medusagynoideae, Quiinoideae and Ochnoideae were included in the study. DNA material of all genera of Ochnaceae, except *Indosinia*, *Perissocarpa*, and *Rhytidanthera*, was obtained. In total, 28 out of about 55 *Campylospermum* species occurring in Africa and Madagascar were sampled. These include 20 West/Central African, four East African and four Malagasy species. Two species of Malpighiaceae, *Heteropterys chrysophylla* (Lam.) Kunth and *Acridocarpus longifolius* (G.Don.) Hook.f., were selected to serve as outgroups.

Table 1. Taxon list with information on herbarium vouchers (herbarium acronym), geographic location and GenBank accession numbers for three DNA regions. Data from additional accessions used in composite taxa are in parentheses; for cultivated material from Botanic Gardens (BG), the garden accession numbers are given.

5.2.2 Character sampling

The dataset was composed of three chloroplast markers: the tRNA intron (*trnL*) and intergenic spacer (*trnL-F*), and two coding regions (*matK* and *rbcL*). The advantage of using these markers is that they all represent single-copy regions. Moreover, several amplification and sequencing primers were developed for these regions and used successfully throughout the dicots. At least at family level, the evolutionary rates of these genes have proven appropriate for resolving relationships.

The universal primers C/D and E/F were used to amplify *trnL-F* (Taberlet et al. 1991). Partial *matK* sequences were amplified and sequenced using primers 400F (Cameron et al. 2001) and 1159R (Wurdack and Davis 2009). Additional newly designed primers were used: *matK*-OCH-F CAT CCA TAT AGA AAA ATT GGT TC and *matK*-OCH-R CGC CAA AGT TTT AAC ACA AGA. Amplification of partial *rbcL* was mostly done in BOLD (www.barcodinglife.org), a web-based service provided by the Canadian Centre for DNA Barcoding. Primer *rbcLa*-F (Levin et al. 2003) and *rbcla*-R (Kress and Erickson 2007) were used. In addition, new primers were designed to sequence degraded samples from herbarium material: 1F-ACTCCTCAACCTGGAGTTCC and 1R-GGATTCTGCAAATCCTCCAGGC; 2F-GCCTGGAGGATTGCGAATCC and 2R-GGGAGTTCACATTCTCATC.

DNA material was extracted from herbarium or silica dried material following an adapted protocol from the cetyltrimethylammonium bromide (CTAB) method (Doyle and Doyle 1987) described in Bakker et al. (1998). Leaf material was ground to a fine dust-like powder using an electric bead mortar. The powder was mixed with the CTAB buffer and incubated at 56 °C before DNA isolation. Isolation was done with chloroform/isoamylalcohol alcohol (24:1). DNA was precipitated in ice-cold isopropanol after been left overnight in the freezer at -20 °C. For herbarium material, with degraded DNA, precipitation time took at least 2 weeks. DNA pellets were washed with a wash buffer (76% ETOH and 10 mM NH₄Ac), air-dried, and resuspended in resuspension buffer (10 mM NH₄Ac and 0.25 mM EDTA). The DNA was precipitated again in a solution containing MQ water, 7.5 µl of NH₄Ac (2.5 M) and cold 96% ETOH (2.5 Vol.). The mixture was left overnight in the freezer at 20 °C. DNA pellets were washed in 70% ethanol, air-dried and resuspended in TE (10 mM Tris, 1 mM EDTA).

PCR reactions were performed with 1-2 µl of DNA template; 1 µl of MgCl₂; 1 µl of BSA; 0.4 µl of dNTP; 0.35 µl of each primer; 0.08 µl of Taq polymerase (Fermentas). For amplification of *trnL-F*, the PCR program was set as: 30 thermal cycles of 94 °C: 50 sec; 53 °C: 50 sec of annealing temperatures; 72 °C: 1.5 min of first extension, with the initial denaturation for 50 sec at 94 °C and the final extension for 7 min at 72 °C. Amplification of *matK*-OCH as: 98 °C: 45 min; 35 cycles of 98 °C:10 sec; 72 °C: 40 sec; final extension 72 °C: 10 min. Amplification of *rbcLa* was as follow: 94 °C: 4 min; 35 cycles of 94 °C: 30

sec; 55 °C: 30 sec; final extension 72 °C: 10 min.

PCR products were cleaned using the MinElute® PCR purification kit (Qiagen), and then sequenced using the Dye ET terminator sequencing kit (Amersham Pharmacia Biotech), running on the ABI Prism 3700 (Greenomics, Wageningen).

Sequences were edited using Staden version 1.7.0 (<http://staden.sourceforge.net/>) and aligned with CodonCode Aligner version 3.7.1 software. Subsequent alignment was done manually when necessary, following the view presented in Kelchner and Clark (1997). Missing characters, indels, microsatellites, and characters the alignment of which was ambiguous were excluded from all analyses.

5.2.3 Phylogenetic analyses

Maximum parsimony (MP)

MP analyses were performed on each of the three markers separately and on the combined dataset using PAUP* version 4.0b10 (Swofford 2003). To search for optimal trees, heuristic searches were done with 100 random sequence addition iterations, saving 10 trees per iteration. Trees resulted from this search were used as starting trees for another round during which they were swapped with a limit of 5000 trees. The strict consensus tree was computed from trees resulting from this search. Support for each node was assessed by performing 1000 bootstrap replications for individual markers. For the combined dataset, support for each node was assessed by performing 2000 replications, 50 random sequence addition replicates, saving no more than 5 trees per replicate. For all parsimony searches the branch-swapping option was set to tree bisection-reconnection (TBR).

The topologies of the bootstrap consensus trees for the three markers were compared by eye. No well-supported incongruences were found, hence the sequence data were concatenated and analysed simultaneously.

Maximum likelihood (ML)

Maximum likelihood analyses were conducted using the RAxML web-server program available at the CIPRES portal V1.0 in San Diego, CA, USA (Cipres Science Gateway; <<http://www.phylo.org/index.php/portal/>>; Miller et al., 2010). RAxML is a sequential and parallel programme for inference of large phylogenies (Stamatakis 2006), and implements efficient and rapid bootstrap heuristics (Stamatakis et al. 2008). Rapid bootstrap analyses and search for the best-scoring ML tree in one single program run was conducted with a random seed value set to default and with 1000 bootstrap iterations.

Bayesian inference

Bayesian analyses were performed using MrBayes version 3.2.1 (Ronquist and

Huelsenbeck 2003) available at the CIPRES portal V1.0. The data matrix was divided into three partitions according to the markers. The *trnL* intron and *trnL*-F spacer were combined as a single partition. The most likely evolutionary model for each partition was identified under AIC scores using FindModel <http://www.hiv.lanl.gov/content/sequence/findmodel/findmodel.html>. The General Time Reversible plus Gamma (GTR+G) substitution model was selected for *trnL*-F. The Kimura 2-parameter plus Gamma (K80+G) substitution model was selected for *matK* and *rbcL*.

Four MCMC runs were made with two independent chains per run, for ten million generations. The default prior settings were used, with a temperature of 0.25. The unlink command was set to allow rates and substitution models to vary across partitions. Trees of all parameter values were sampled every 1000th generation. Convergence of the runs was checked using both the values for effective sample sizes (ESS) using Tracer version 1.5 (Rambaut and Drummond 2013) and the cumulative clade posterior probabilities (PP) using the online programme AWTY (J. A.A. Nylander et al. 2008). The initial 25% of generations were discarded as burn-in and a consensus tree was generated from the remaining trees.

5.3 Results

Poecilandra and *Schuurmansielia* could not be amplified due to poor quality of their DNA extractions. A total of 87 terminal taxa were aligned including two outgroup taxa. The combined data matrix produced 2287 sites.

Table 2 summarizes the tree statistics for the MP analysis. The MP tree topology was not resolved and showed several big polytomies. ML and Bayesian analyses yielded highly similar results revealing the monophyly of the Ochnaceae (BS 100%; PP=1). The only incongruence between the two topologies was that a clade comprising *Ochna* and *Brackenridgea* taxa was retrieved (Fig. 2) in the ML analysis, although with weak support (BS 38%). This clade was not recovered in the Bayesian analysis. The backbone of the tree is strongly supported in all analyses. The three subfamilies Ochnoideae, Quiinoideae and Medusagynoideae are retrieved as clades with good support. The tree topology shows that Medusagynoideae is sister to the two other subfamilies. Quiinoideae is well supported with 89% BS and 0.96 PP (Fig. 2). *Froesia* is inferred as sister to a well-supported clade of *Quiina*, *Touroulia* and *Lacunaria* (100% BS, 1 PP).

Testulea gabonensis Pellegr. is sister to the rest of the Ochnoideae, which is overall well resolved with the exception of the clade including the Ochninae species, which received only 43% bootstrap support and 0.80 Bayesian probability (Fig. 2).

The tribes Luxemburgieae and Sauvagesieae as well as the subtribes Lophirinae and Elvasiinae are resolved and well-supported (100% BS and 1 PP) (Fig. 2).

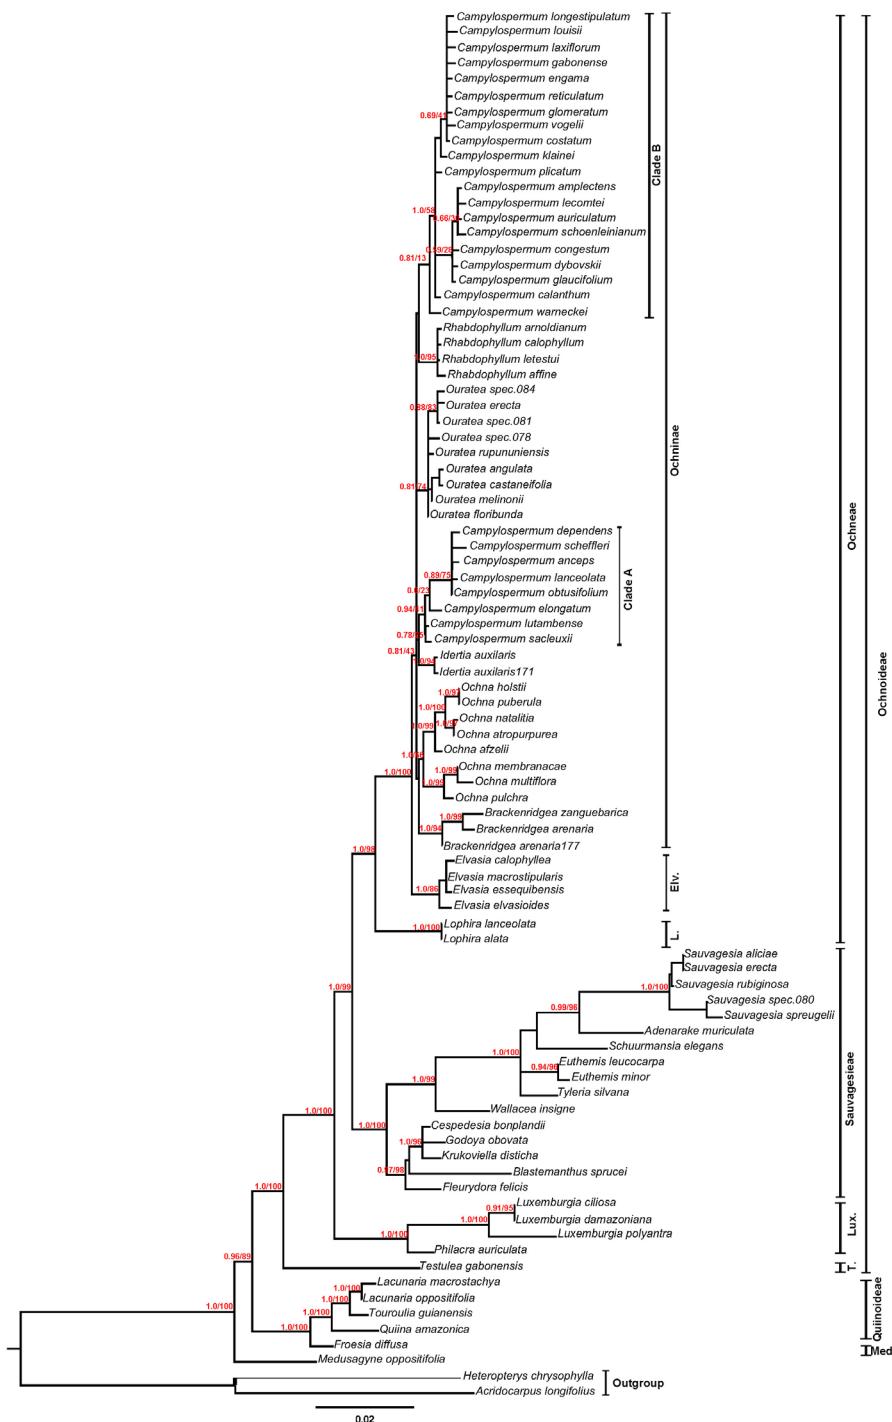

Figure 2. Maximum likelihood tree of Ochnaceae based on the combined DNA regions with posterior probabilities obtained from Bayesian inference and bootstrap support from RAxML analysis. Elv. = Elvasiinae; L. = Lophirinae; Lux. = Luxemburgieae; T. = Testuleeae (sensu to Schneider et al 2014).

Within the subtribe Ochninae, the genera *Brackenridgea*, *Idertia*, *Ochna* and *Rhabdophyllum* are all well-supported (PP = 1.0), while *Ouratea* receives 74% BS and 0.81 PP. However, relationships among these genera are mostly unresolved; most strikingly the genus *Campylospermum* is split into two clades. One clade comprises the Malagasy and East African *Campylospermum* spp. plus *C. elongatum* from West/Central Africa (clade A) and retrieved in the ML analysis with weak support (41% BS) but with good support in the Bayesian analyses (0.94 PP). This clade is sister to *Idertia*, though with weak support (25% BS, 0.78 PP). The second clade groups the West/Central African *Campylospermum* species (except *C. elongatum*) (clade B) as sister to either *Rhabdophyllum* in the ML tree or in a polytomy with the remainder of the Ochninae in the Bayesian tree.

Table 2: Tree statistics of both individual and combined markers. CI = consistency index; RI = retention index. Outgroup taxa were included in the calculations.

Marker	matK	rbcLa	trnL-F	Combined
# of taxa	63	120	99	91
# of characters in the aligned matrix	760	551	986	2287
# of excluded characters in the aligned matrix	12		18	30
CI	0.69	0.44	0.73	0.65
RI	0.79	0.69	0.85	0.77
#constant characters	464	438	538	1579
# of parsimony-informative characters (%)	153 (20.13%)	68 (12.34%)	195 (19.77%)	374 (16.35%)

5.4 Discussion

This discussion will follow the recent circumscription of Ochnaceae based on Schneider et al. (2014), given the need of a stable classification (Godfray and Knapp 2004), and the fact that the APG III classification (APG III 2009) is widely accepted and adapted in recent flora works (Fiaschi et al. 2010), classifications (Maddison and Schulz 2007) and databases such as .

The present study confirms the backbone of the phylogeny presented by Schneider et al. (2014), which was based on a combined data set of chloroplast and nuclear DNA. Not surprisingly, this combined data set gives a better-resolved tree than ours that was derived from chloroplast data only. In general, the addition of characters has a beneficial effect on phylogenetic inference (Hillis et al. 2003; Rosenberg and Kumar 2003) but when the additional marker has a different phylogenetic history there is no relationship between the addition of characters and an increase of support values (Wiens 1998).

Therefore, we conclude that within Ochnaceae the maternally inherited chloroplasts share their history with the nuclear material, indicating that hybridization has not played a major role in the evolutionary history of the extant main clades.

From the tree topology and support values we conclude that the Ochnaceae is a monophyletic family, which is congruent with the results of Schneider et al. (2014). A significant incongruence is that the current study infers Medusagynoideae as sister to the rest of the family, whereas it is closely related to the Quiinoideae in Schneider et al. (2014), but with low support (73% BS, 0.67 PP). Our analyses show high support at the relevant nodes. This would imply that the nuclear (ribosomal) sequences are not congruent with the pattern provided by the chloroplast DNA. The second subfamily, the Neotropical Quiinoideae, is well resolved.

Our results inferred from the MP analysis show a large polytomy at the base of the subfamily Ochnoideae. This is unexpected, regarding the high support in both the ML and Bayesian analyses for the vast majority of the major Ochnoideae clades. However, branch lengths are very short and, apparently, the MP analysis yielded several other tree topologies that were equally short in terms of number of character state changes. We decided not to analyse all other topologies, but simply discard the MP results and continue with the ML and Bayesian tree topologies.

Well-supported clades inferred by Schneider et al. (2014), and recognized as tribes and subtribes, are also retrieved by the current study. The tribe Luxemburgieae consists of the Neotropical genera *Philacra* Dwyer (4 spp.) and *Luxemburgia* A.St.-Hil. (18 spp.) and was treated as a subtribe of the Sauvagesioideae by Kanis (Kanis 1968). We thus confirm the recognition of this clade as a tribe within the subfamily Ochnoideae, following Schneider et al. (2014). Well-supported relationships are also found within the tribe Sauvagesieae, which comprises species from the Old and New World tropics as well as South-East Asia. The position of *Fleurydora* (a monotypic genus endemic to the tip of West Africa), however, as sister to a clade composed of the Neotropical genera *Blastemanthus* Planch., *Cespedesia* Goudot, *Godoya* Ruiz & Pav. and *Krukoviella* A.C.Sm. conflicts with Schneider et al. (2014). It should be noted, however, that relationships among the early-diverging lineages in the Sauvagesieae are generally poorly supported in Schneider et al. (2014). Moreover, the sampling in Schneider et al. (2014) of these lineages is slightly larger than ours, further confounding comparison. The latter genera share several features such as the same texture and shape of the sepals and anthers, pistil position at anthesis and the intrusive T-shaped parietal placentae bearing several imbricate ovules (Dwyer 1944). *Fleurydora*, in turn, is morphologically related to these New World genera through the placentation pattern (Dwyer 1944), although other characteristics place *Fleurydora* closer to *Poecilandra* (not sampled here). The leaf blades of *Fleurydora* and *Poecilandra* are similar in shape, and have a retuse apex, the

sepals are similarly disposed, the style is subulate (Dwyer 1944). This conflict between the outcomes of the two studies regarding the position of *Fleurydora* suggests that the markers do not yield sufficient variation, or that the different partitions carry conflicting evidence. A more detailed study on these aspects is advised.

Within the tribe Ochnae, the position of the subtribes Elvasiinae, Lophirinae and Ochninae strongly agree with the topology presented by Schneider et al. (2014). In the subtribe Ochninae relationships are poorly resolved. *Brackenridgea* and *Ochna*, which share a number of morphological characters (see above), formed a single clade in the ML tree but both genera appear in two different clades in the Bayesian tree (Fig. 2). They formed the subtribe Ochninae sensu Kanis, based on pollen and flower characters. Their alleged close relationship is not supported by the analyses of Schneider et al. (2014), which showed *Brackenridgea* being sister to *Idertia*. Although morphological characters support a relationship of *Brackenridgea* with *Ochna* and not with *Idertia*, for now, we adopt the generic configuration of the study of Schneider et al. (2014).

Although relations within the subtribe Ochninae are generally not well resolved, our extended sampling of *Campylospermum* species has led to the retrieval of two distinct clades within this genus. The first (clade A) groups the East African and Malagasy *Campylospermum* species, together with *C. elongatum* from West/Central Africa, while a second clade (clade B) comprises all other West/Central African species (Fig. 2). Clade B is, depending on analysis, retrieved as sister to *Rhabdophyllum* or grouped along in a polytomy with the rest of the Ochninae genera. Clade A, however, is sister to *Idertia* rather than to the *Campylospermum* species in clade B. This split of *Campylospermum* species into two clades might be the result of speciation via long distance dispersal facilitated by the presence of the Comores and Seychelles/Mascarenes, that could have acted as stepping-stones for dispersal between Africa and Madagascar and between Madagascar and Asia, respectively (Warren et al. 2010; Buerki et al. 2013). Moreover, members of clade A share a distinct reticulate tertiary leaf venation, and accumbent embryos that are similar in size. They generally have (except for *C. lutambense*, which is only known from four specimens) an axillary inflorescence. The latter character might indeed link *Idertia* to this clade and therefore could represent a potential synapomorphy of clade A plus *Idertia*. Members of clade B have a terminal inflorescence (except for *C. oliveri*, *C. subcordatum*, *C. duparquetianum*) while the embryos can be similar/dissimilar in size and accumbent/incumbent. However, most of the above remains speculative, since the relevant nodes have only weak support and branch lengths are very short. To test these hypotheses, an even more extensive sampling of African, Malagasy and Asian species (absent from both studies) and additional gene sequences would be required. This would, firstly, provide phylogenetic support for the recognition of different clades within *Campylospermum*, and for the establishment of new nomenclatural combinations when necessary. Secondly, this phylogeny would serve as a framework to test which historical events have affected the current distribution of *Campylospermum* clades and species.

5.5 Conclusion

We confirm the recognition of the three subfamilies Medusagynoideae, Quiinoideae and Ochnoideae as distinct clades, as well as do the tribes Luxemburgieae, Ochneae, Sauvagesieae and Testuleeae. The markers *matK*, *rbcL* and *trnL-F* appear to be less suitable to depict evolutionary relationships of Ochnaceae at the genus level. The backbone phylogeny within the subtribe Ochninae is poorly resolved, impeding further biogeographical and evolutionary studies. Additional taxa and sequence data are required to further resolve the phylogenetic relationships within Ochninae, notably the interesting split of the genus *Campylospermum* into an East Africa/Madagascar and a West/Central Africa clade.

Abstract

Ochnaceae is a family of trees, shrubs or rarely herbs, widely distributed in tropical and subtropical forests and savannas of the Old and New World, and comprises about 500 species in 27 genera. The family is divided into Medusagynoideae, endemic to the Seychelles, the Neotropical Quiinoideae, and the pantropical Ochnoideae. Whether the distributional disjunctions within the Ochnaceae are consistent with an early-Cretaceous Gondwanan break-up scenario or with one involving more recent long distance dispersal has not yet been tested. In general, three routes have been documented for the dispersal of taxa between the Palaeotropic and Neotropic regions: via the North Atlantic Land Bridge, via the Bering Land Bridge and from America directly to Africa, or vice versa, involving long distance dispersal. Dating analyses were performed using five DNA sequence regions (ITS, *matK*, *ndhF*, *rbcl*, *trnLF*), a secondary calibration, and relaxed molecular clock models. The historical biogeography of Ochnaceae was reconstructed using Dispersal-Vicariance Analysis and Bayesian Binary MCMC. We inferred a mean age of crown group Ochnaceae of 77.7 Ma. The Neotropics were inferred as the origin of the family (83.5 % marginal probability) and the Old World was most likely colonized via the North Atlantic Land Bridge when climatic conditions allowed establishment of a boreotropical flora. Subsequently, migrations back to South America (*Ouratea*) and independent dispersal of Sauvagesieae and Ochneae lineages to Africa and Asia occurred. According to our age estimates, vicariance can be ruled out as a mechanism to explain the transoceanic disjunctions.

Keywords: biogeography, dispersal, Malpighiales, molecular clock, Ochnaceae, vicariance

6.1 Introduction

Angiosperm biogeography and past continental movement have been the subject of many studies that involve patterns of species distribution across the globe (Tiffney and Manchester 2001; Donoghue and Moore 2003; Wiens and Donoghue 2004; Renner 2005; Nathan et al. 2008; Antonelli et al. 2009). With the advancement of molecular analyses and fossil evidence, increasing numbers of continental disjunctions have been analyzed (Tiffney & Manchester 2001, Richardson et al. 2004; Nicolas & Plunkett 2014). These generally propose vicariance and long distance dispersal as the two hypotheses that can explain these disjunctions. In Myrtaceae, for example, it has been postulated that this family has an Australian origin and migrated to South America through the Australasia-Antarctica-South America land mass (Sytsma et al. 2004). Likewise, the diversification of major clades of Apiales seems to be affected by vicariance events (Nicolas and Plunkett 2014), because the divergence time at the split between Torricelliaceae from Griseliniaceae and Apiinae nicely coincides with the break-up of Africa and Australasia (Nicolas and Plunkett 2014). On the other hand, age estimates of many angiosperm clades are relatively young (Wikström et al. 2001; Magallón et al. 2005; Bell et al. 2010), dating back to at least after the complete separation of landmasses that have led to the current position of the earth's continents. This suggests that disjunct distribution patterns of such clades cannot exclusively be explained by vicariance and one has to consider long distance dispersal as an alternative explanation. Although, for example, the disjunct distribution of Annonaceae and Myristicaceae may have involved vicariance events (Doyle et al. 2004), most clades within Annonaceae are too young (Richardson et al. 2004), for instance *Guatteria* (Erkens et al. 2009) and *Anaxagorea* (Scharaschkin and Doyle 2005), and their distribution patterns therefore invoked long distance dispersal. (Morley 2003) has reviewed dispersal routes that may have played a role in many tropical intercontinental disjunctions. Most of these routes existed in the Late Cretaceous and Late Tertiary. Examples are the North Atlantic Land Bridge (NALB) connecting Europe and North America, or the Bering Land Bridge (BLB) connecting Asia and North America. Renner (2004) nicely pointed out the role of sea currents and prevailing wind directions as being the vectors responsible of the trans-oceanic disjunct distribution of genera occurring on both sides of the tropical Atlantic. She listed about 110 genera with a transatlantic distribution, and hypothesize that trans-oceanic dispersal from South America to Africa was influenced by wind, while dispersal from Africa to South America involved sea currents.

A third hypothesis to explain the disjunct distribution ranges of extant taxa is the boreotropical scenario, which hypothesizes that some tropical disjunctions may have arisen as a result of boreotropical migration. The boreotropical flora was hypothesized to extent across the northern hemisphere its climate supported tropical vegetation

(Wolfe 1975; Tiffney 1985). This took place during the episodes of global warming from 59 Ma to 52 Ma, with a peak around 50 Ma in the Early Eocene Climatic Optimum/EECO (Zachos et al. 2001). The EECO was followed by a period with slowly decreasing temperature, which lasted for about 17 mya (Zachos et al. 2001). The further cooling of global climate forced the boreotropical vegetation to move to lower latitudes to finally form tropical and subtropical disjunction pattern of taxa extant today. This hypothesis was proposed to explain the disjunctive distribution pattern of, among others, Annonaceae (Richardson et al. 2004), Magnoliaceae (Nie et al. 2008) and Malpighiaceae (Davis et al. 2002).

Ochnaceae s.str. is, like most of the families within the order Malpighiales, widely distributed in tropical and subtropical forests and savannas of the Old and New World (Amaral and Bittrich 2014). It is a family of trees and shrubs or rarely herbs and consists of about 500 species in 27 genera. The highest species richness is found in the Neotropics, where 250–300 species and 15 genera are present (Schneider et al. 2014). In Africa, including Madagascar, about 150 species and nine genera occur, while the lowest diversity is observed in Southeast Asia, hosting only 20 species and 8 genera (Kanis 1968; Verdcourt 2005). The majority of the genera is confined to a single continent, exceptions being *Campylospermum* and *Ochna*, both with an Old World distribution (Bissiengou et al. 2013), and the pantropical *Sauvagesia*, although the latter is demonstrably non-monophyletic in its current delimitation (Schneider et al. 2014).

Phylogenetic studies based on DNA sequence data placed Ochnaceae s.str. in the order Malpighiales as a sister family to both Medusagynaceae and Quiinaceae (Fay et al. 1997; Davis et al. 2005; Korotkova et al. 2009; Wurdack and Davis 2009; Xi et al. 2012). A recently published comprehensive molecular phylogenetic analysis and updated classification of Ochnaceae (Schneider et al. 2014) united the three families to form an expanded Ochnaceae s.l. (from now on referred to as Ochnaceae), which consists of three subfamilies: Medusagynoideae Reveal, Quiinoideae Luerss. and Ochnoideae Burnett. Medusagynoideae are monotypic and endemic to the Seychelles. Quiinoideae comprise only Neotropical species. Ochnoideae contain species from both the New and Old Word tropics.

The historical biogeography of Ochnaceae has never been the subject of a detailed study because a comprehensive molecular phylogenetic hypothesis was lacking. Yet, the family contains many interesting distribution patterns. In the Neotropics, Ochnaceae are distributed in Central and South America; while Central America is poor in species, many endemic species, mainly of the genus *Ouratea*, are found in northern South America (Sastre 1987). In Africa, Ochnaceae are found in the tropical regions of West, Central, East and South Africa (though not in the southern part of South Africa where a Mediterranean climate prevails). Only few species occur in Madagascar and

surrounding islands (Seychelles and Mascarenes) as well as in the Indo-Pacific region and Southeast Asia. In the subfamily Ochnoideae, the tribe Ochneae is divided into the subtribe Ochninae and the monogeneric subtribes Elvasiinae and Lophirinae from America and Africa respectively. Ochninae comprises the strictly African genera *Idertia*, *Rhabdophyllum*, the palaeotropical genera *Campylospermum*, *Brackenridgea* and *Ochna*, and the neotropical genus *Ouratea*, depicting an amphi-Atlantic relationship within Ochninae. In the tribe Sauvagesieae, however, the majority of genera are from the Neotropics while few are found in tropical Asia, one in Africa (*Fleurydora*) and *Sauvagesia* which is present on three continents. Kanis (1968) hypothesized that its subfamily Sauvagesoideae (now tribe Sauvagesieae) originated in the Neotropics, and that the occurrence of Asian taxa within this clade depicted amphi-pacific relationships rather than a migration via Africa. We would probably not arrive at the same conclusions now that the African genus *Fleurydora* has been included in the Sauvagesieae.

Davis et al. (2005) estimated the age of the stem node of the Ochnaceae ranging from 98.8 to 116.6 Ma. Their sampling was limited to single species of the genera *Quiina*, *Medusagyne*, *Ochna* and *Cespedesia*, which together were retrieved as a clade, sister to a clade uniting Phyllanthaceae and Picrodendraceae, without any data support, however. Xi et al. (2012) inferred the ages of nodes in Malpighiales and the following Ochnaceae genera were included: *Medusagyne*, *Froesia*, *Touroulia*, *Quiina*, *Luxemburgia*, *Sauvagesia*, *Cespedesia*, *Lophira*, *Elvasia*, *Ochna*. The mean crown node age of the Ochnaceae was estimated at 77.8 Ma. The lower end of the 95% highest posterior density interval of the Ochnaceae crown node age extends back to 90.5 Ma. As discussed above, three hypotheses account for many of the present-day disjunctions seen in various groups of tropical flowering plants. Given the separation of the Madagascar-Antarctica-India landmass from the Africa-South America landmass (around 135Ma) and the break-up of Africa and South America (around 100 Ma), vicariance, does not seem very likely in view of the age of the Ochnaceae crown node (Davis et al. 2005; Xi et al. 2012). We therefore hypothesize that boreotropical migration and long distance dispersal has been the major driving force for the contemporary cross-continental distribution patterns in Ochnaceae.

In the present study, the comprehensive molecular phylogeny of Ochnaceae s.l. (Schneider et al. 2014) is used to (1) investigate its area of origin, and (2) test which of the above mentioned scenarios could be postulated to explain the present disjunct distributions in Ochnaceae.

6.2 Material and Methods

6.2.1 Taxon sampling

The dataset used in this study is similar to that used by Schneider et al. (2014) and includes all genera of Ochnaceae s.l. except *Indosinia* and *Perissocarpa*. Our final taxon sampling includes 78 accessions (see Table 1 in Schneider et al. 2014).

6.2.2 DNA sequencing

The DNA sequences of the gene regions ITS, *matK*, *ndhF*, *rbcL* and *trnLF* were obtained from Schneider et al. (2014). DNA extraction, PCR and sequencing, and alignment methods are all as described in that paper.

6.2.3 Dating analysis

Taxon sampling strategy

Molecular dating analyses can be subjected to many sources of error. It has been demonstrated that increasing or decreasing the number of taxa in a dataset can result in different time estimates, being the result of the combined effect of under-sampling and either distance from the calibration node (Linder, Hardy, et al. 2005) or positions of calibration points (Xiang et al. 2011). A further problem, and therefore a possible source of error, is the way dating analyses model substitution rate heterogeneity, i.e. the extent to which substitution rates depart from a strict molecular clock, and how this heterogeneity is distributed over different data partitions and/or different lineages. There have been several analytical approaches to dealing with heterogeneous rate distribution among sites and data partitions. One commonly used approach has been the assumption of autocorrelation, viz. the inheritance of substitution rates from parent to daughter lineages (Sanderson 1997; Drummond and Suchard 2010). In cases where the assumption of rate autocorrelation is violated, Bayesian relaxed clock models perform better (Drummond et al. 2006). These methods reduce the stringency of autocorrelation by drawing substitution rates from a continuous prior distribution (Drummond et al. 2006). Relaxed clock methods, however, have been shown to be incapable of modelling substitution rate heterogeneity over lineages (Dornburg et al. 2012; Wertheim et al. 2012). For an entire dataset this may result in posterior substitution rate distributions showing a multimodal pattern. A possible signature of this problem in phylogenetic trees is the clade-specific distribution of branch lengths, visible in plant groups such as Annonaceae (Chatrou, Erkens, et al. 2012; Chatrou, Pirie, et al. 2012) and Lentibulariaceae (Jobson et al. 2003). Such a clade-specific distribution of branch lengths also appears from phylogenetic analyses of Ochnaceae (Schneider et al. 2014), with the Ochneae being characterized by distinctly shorter branch lengths than the Sauvagesieae. We hypothesize that this tree shape and branch length distribution

is caused by clade-specific differences in substitution rates, and here investigate its possible effect on the estimation of node ages in Ochnaceae. To test this we analyzed three data sets. Node ages were estimated analyzing the entire data set as well as two smaller subsets: a long-branch and short-branch one. The long-branch subset kept two of Sauvagesieae accessions and included all Ochneae. The short branch subset kept two of Ochneae accessions and included all Sauvagesieae. This was done to have the crown nodes of both clades included in the analysis, whilst minimizing the effect of the minimal represented clade on the estimation of substitution rates. The two accessions of both clades were chosen in such a way that the crown node was bracketed. The long-branch subset comprises 61 accessions and the short-branch 38. Data sets were compiled using the programme Mesquite version 2.75 (Maddison and Maddison 2011). Each subset used the same alignment as in the complete matrix of 78 accessions, but gaps were removed so as not to bias the estimation of branch lengths by the presence of missing data.

Fossils

Unfortunately, there are no fossil records of Ochnaceae. Pigg et al. (2005) report on a fossil fruit of uncertain age that resembles *Ochna*. However, comparing their fossil to modern Ochnaceae, notably the presence of a scar/groove on the fossil and way the nutlets/drupelets are attached and compacted is not reminiscent of Ochnaceae. Therefore, we reject this fossil as belonging to Ochnaceae. Furthermore, Danehy et al. (2007) described fossil Ochnaceae leaves from Mississippi as *Rhabdophyllites diapyros*. Based on the combination of the type of leaf venation and a toothed margin, they suggested the fossil would be similar to the genera *Rhabdophyllum*, *Philacra*, and *Schuurmansiella*. Having studied the taxonomy of Ochnaceae extensively in the field and in herbaria, we note that closely spaced secondary veins are always connected by percurrent tertiary veins in the family, while the fossil shows a reticulate pattern of tertiary venation. In *Rhabdophyllum*, to which the fossil has been linked by Danehy et al. (2007), the secondary veins run almost straight to or only slightly curved/oblique to the margin, in which they terminate, while the margin itself is thickened and produces small setae. So, laterals do not, as in the fossil, peter out toward the margin, eventually running almost parallel to it, and do not end in an actual tooth. The marginal teeth in *Rhabdophyllum* are in fact more rounded. Therefore, we also discarded *Rhabdophyllites diapyros* as being a close relative of *Rhabdophyllum*.

Divergence times

Divergence time estimations were performed using the BEAST (Bayesian Evolutionary Analysis Sampling Trees) software package, version 1.7.5 (Drummond et al. 2012). The dataset was partitioned according to the gene regions. Clock and substitution models were estimated separately for each of the five regions. The substitution model was set to

GTR, the site heterogeneity model to Gamma, which allows rate variation between sites in the alignment (Drummond et al. 2012). To estimate the clock rates and divergence times, the uncorrected lognormal clock model and the calibrated Yule model was specified as the tree prior.

In order to estimate the divergence times within Ochnaceae, we calibrated the crown node of the Ochnaceae with a mean age of 77.8 Ma (from Xi et al. 2012), a normal prior distribution and a standard deviation of 0.5. This results in a range of possible ages from 90.5 to 61.3 Ma, which corresponds to the confidence interval reported by Xi et al. (2012) for the crown node of the Ochnaceae. Age estimates of the clade Ochnoideae were not used because of incongruence between their data and ours in terms of taxon sampling.

During the MCMC analysis, three independent chains of 35 million generations were run, sampling trees and parameters every 1000 generations. Convergence of the model parameters among the three chains was checked by visual inspection of the trace plots of LnL, by assessing the effective sampling size (ESS) for all parameters using Tracer versions 1.6 (Rambaut and Drummond 2013), and by visual inspection of cumulative clade posterior probabilities using AWTY (J. A.A. Nylander et al. 2008). The mean node ages and highest posterior density interval (HPD) of divergence time estimates were summarized using TreeAnnotator v1.7.5 (Drummond et al. 2012). The results were visualized using Figtree v1.4.0 (Rambaut 2012).

Ancestral area reconstruction analyses

In the phylogeny of Ochnaceae derived from Schneider et al. (2014) several relationships remain unclear due to low support values. For example, Ochnoideae were inferred as sister to a clade of Medusagynoideae and Quiinoideae with weak support values, and hypotheses about the relationships within Ochninae received only low support. To accommodate these uncertainties, the software Reconstruct Ancestral State in Phylogenies (RASP) developed by Yu et al. (2013) was used to reconstruct the ancestral ranges of Ochnaceae. RASP implements three methods, Statistical Dispersal-Vicariance Analysis (S-DIVA), Bayesian binary MCMC (BBM) and maximum parsimony (MP) analysis. S-DIVA and BBM determine alternative ancestral ranges at each node and calculated posterior probabilities for each ancestral range at each node. This approach is advantageous compared to DIVA developed by Ronquist (1997, 2001), which reconstructs ancestral ranges onto a fixed phylogenetic tree assuming to be without error (J. A. A. Nylander et al. 2008). Furthermore, although Nylander et al. (2008) showed the utility of a non-parametric empirical Bayesian approach to DIVA (Bayes-DIVA), RASP has the advantage to evaluate alternative ancestral range in a probabilistic framework and thus complements DIVA and Bayes-DIVA. In conclusion, we prefer to use RASP.

Most of the distribution area of Ochnaceae is covered by the taxa we sampled. The distribution areas were based on the current distribution of the terminal taxa and were circumscribed using geological criteria as defined in other studies (such as (Sanmartín and Ronquist 2004; Buerki et al. 2011; Smedmark et al. 2014). Different micro-continents were included within a larger landmass when they shared a similar biota or relatively recent land connections. Four geographical areas were defined (Fig. 1): (A) America, including tropical South America, Central America and the Caribbean region, (B) Africa (continental sub-Saharan Africa), (C) Asia (comprising including South and Southeast Asia, from India/Sri Lanka to Thailand, Malaysia and Indonesia to New Guinea), (D) Madagascar (including the Comoro islands, Mascarene Islands and the Seychelles). Since the Precambrian, the Mascarenes and Seychelles have been connected, in the Indian Ocean, by a contiguous block of thick crust (Torsvik et al. 2013).

Distribution areas of the outgroups were not coded because they are widely distributed (Europe, Australia and North America) also in regions where the ingroup is not present. In the BBM analyses, the outgroups were therefore coded under the wide distribution. This allows RASP to virtually assign an outgroup to any distribution area occupied by the ingroup. To account for phylogenetic uncertainty, 6001 trees from the BEAST output were used. The number of maximum areas was kept at six. The MCMC chains were set to 10 and ran for 50,000 generations. The state was sampled every 100 generations under the fixed Jukes-Cantor+Gamma (JC+G) model. All distribution states are listed in Table 1.

6.3 Results

6.3.1 Dating analysis

Taxon sampling

Age estimates from the two subsets show no significant difference compared to estimates from the main dataset. The 95% confidence intervals of age estimates for the major clades overlap (Table 2). Hence, we assume no effects of long or short branches on the divergence time estimations (see supplements S1 and S2).

Table 2. Mean nodal ages and their 95% confidence intervals of major Ochnaceae taxa. Column two and three provide the figures for the analyses on the two subsets (explanation see text).

Clade	Matrix		
	78 accessions	61 accessions	38 accessions
Medusagynoideae-Quiinoideae	64.7(42.6-77.5)	67.8(54.8-77.7)	67.9(49.4-78.2)
Quiinoideae	19.1(11.7-27.2)	21.6(14.3-29.4)	17(10.6-24.1)
Ochnoideae	69.5(63.5-74.6)	68.1(60.1-75.2)	69.3(62.1-75.5)

Luxemburgieae	20.1(11.1-29.6)	21.7(12.5-31.4)	19.4(10.6-29.6)
Sauvagesieae	41.8(29.7-49.4)	32.6(23.1-43.0)	43.5(35.9-51.5)
Ochneae	36.3(22.5-48.4)	35.3(27.0-44.3)	33.3(19.7-47.8)
Elvasiinae	9.1(2.6-15.5)	10.2(5-15.9)	Pruned
Ochninae	15.0(11-20.6)	16.5(12.5-20.3)	Pruned

Divergence times

All BEAST MCMC runs yielded values for effective sampling sizes >200 for all parameters, indicating convergence. All runs converged on a tree topology highly congruent with the phylogenetic tree of Ochnaceae s.l. recently obtained by Schneider et al. (2014). With the mean age of the Ochnaceae crown node set at 77.8 Ma (95% confidence interval: 76.8–78.7 Ma), the mean age estimate for the clade comprising Medusagynoideae and Quiinoideae is 64.7 Ma (95% confidence interval: 42.6–77.5 Ma; Fig. 2, node 2). The origin of Ochnoideae has an age estimate of 69.5 Ma (95% CI: 63.5–74.6 Ma; Fig. 2, node 4). The split between the clade Luxemburgieae and the rest of the Ochnoideae is dated around 55.1 Ma (95% CI: 42.3–63.8 Ma) whereas the Luxemburgieae are dated around 20.1 Ma (95% CI: 11.0–29.6 Ma; Fig. 2, node 5). Sauvagesieae have an estimated age of 41.8 Ma (95% CI: 29.7–49.4 Ma; Fig. 2, node 6). The Ochneae clade has an estimated age of 36.3 Ma (95% CI: 22.5–48.4 Ma; Fig. 2, node 9).

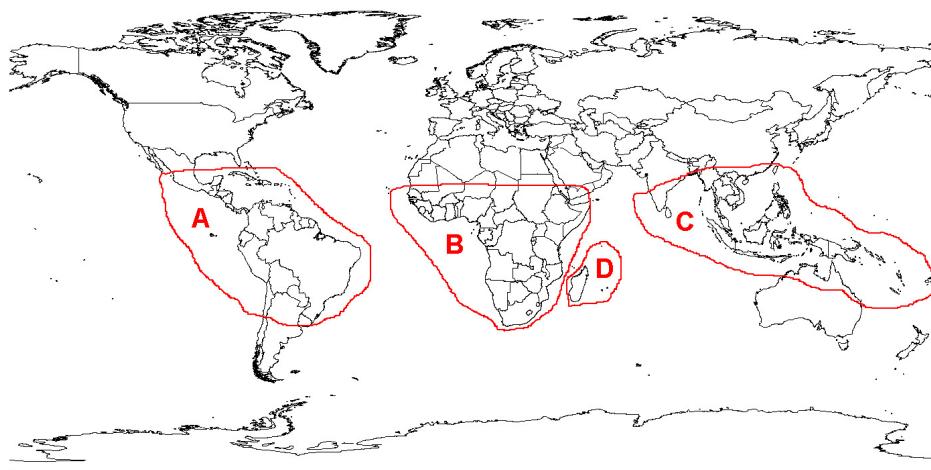

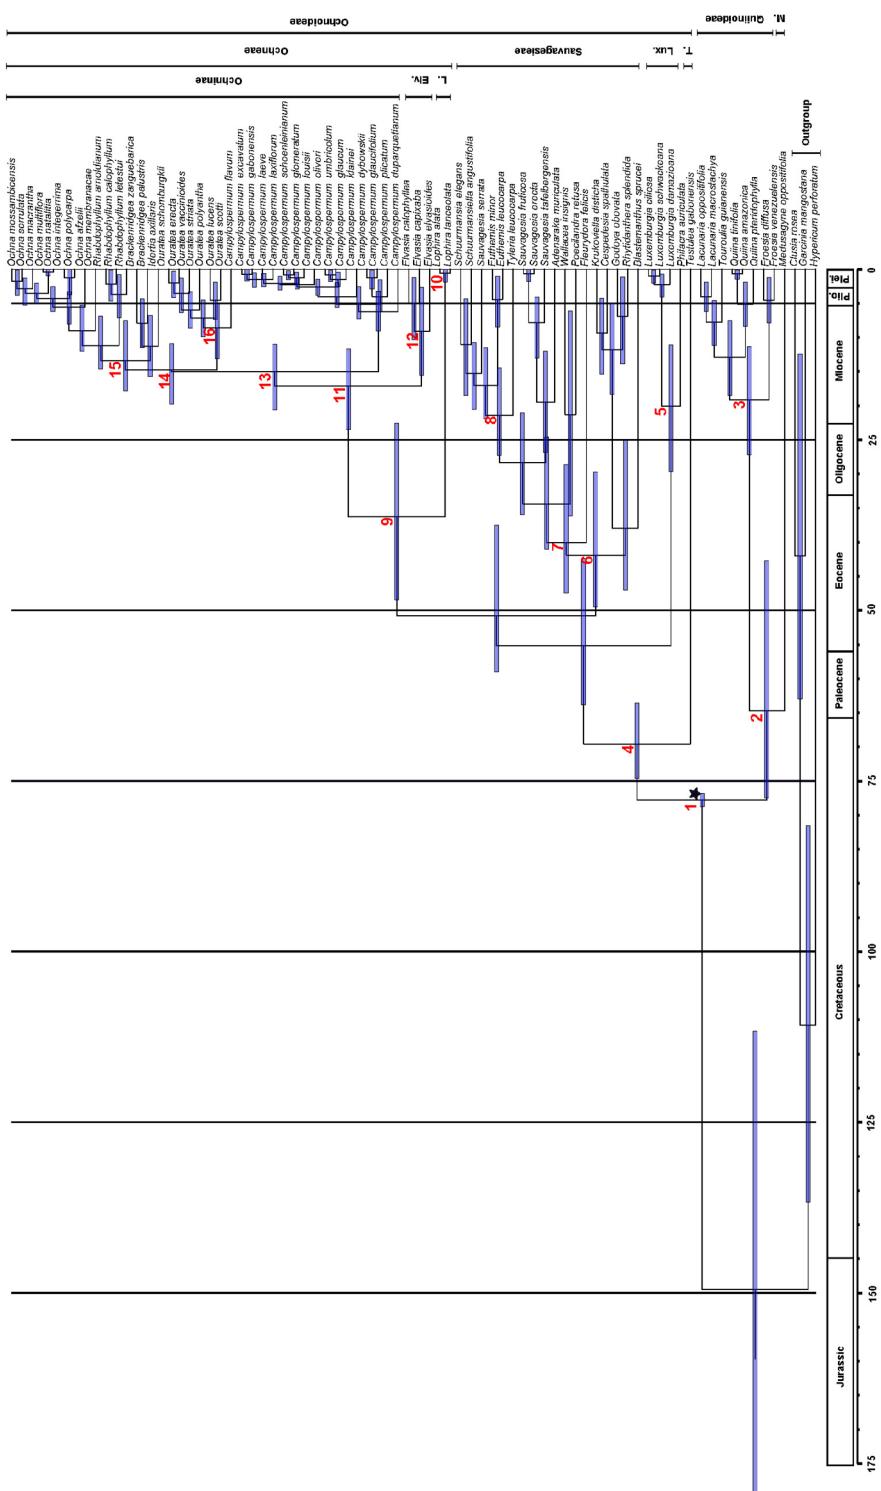

Figure 1: Biogeographical regions.

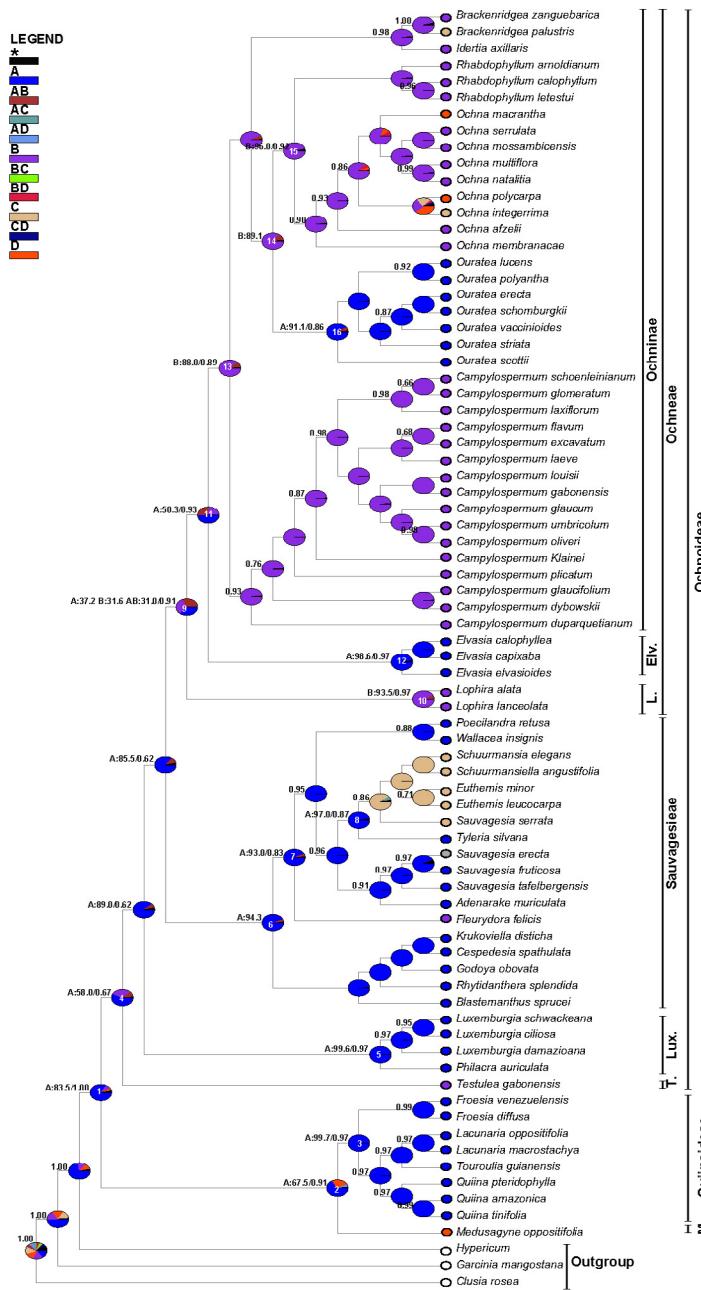

6.3 Results

Figure 2: Chronogram of Ochnaceae as inferred by BEAST. Bars indicate 95% highest posterior density interval (HPD) of the node age. The node numbers are also used in figure 2 and indicate Ochnaceae main subdivisions (subfamilies, tribes, subtribes) or nodes discussed above. Star indicates the calibrating point.

Ancestral area reconstruction

The results of the biogeographic analyses suggested a minimum of 28 dispersal and 14 vicariance events to explain the current distribution of Ochnaceae (Fig. 3). RASP inferred that the modern Ochnaceae originated in America (A) with a marginal probability of 83.5 % (Fig. 3, node 1).

All backbone nodes are also inferred with an origin in America (A). Node 2 is the crown node of Medusagynoideae and Quiinoideae, has a marginal probability of 67.5% and the RASP analysis indicates that a vicariance event took place at this node. The MRCA of Ochnoideae (Node 4) has a marginal probability of only 58.0 %. The RASP analysis suggests a vicariance event has also taken place at this node. Node 5 represents members of Luxemburgieae and the ancestor at this node originated in America (A) with a probability of 99.6 %. The ancestral reconstruction at node 9 (clade Ochneae) is ambiguous; three ranges, A (37.2 %), B (31.6 %) and AB (31.0 %), are reconstructed. The ancestral areas of the most important nodes in terms of taxonomic classification are represented in table 3.

Table 3. Marginal probability of reconstructed ancestral areas for selected nodes in the phylogeny of the Ochnaceae. Node numbers correspond to those in Figure 3.

Node number	Clade	Ancestral area	Marginal probability (%)
(1)	Crown Ochnaceae	Neotropics	83.5
(2)	Medusagynoideae-Quiinoideae	Neotropics	67.5
(3)	Quiinoideae	Neotropics	99.7
(4)	Ochnoideae	Neotropics	58.0
(5)	Luxemburgieae	Neotropics	99.6
(6)	Sauvagesieae	Neotropics	94.3
(9)	Ochneae	Neotropics/Africa/ Neotropics-Africa	37.2/31.6/31.0
(10)	Lophirinae	Neotropics	93.5
(12)	Elvasiinae	Neotropics	98.6
(13)	Ochninae	Africa	88.0

6.4 Discussion

Age estimates can be influenced by different sources of errors potentially present at many of the steps in the process of molecular dating. Our dating analyses are not exempted from these potential problems. For example, fixing the calibration point at the crown node (node 1) resulted in an estimation of the age of the root node at around 150 Ma, which is comparatively old as the first appearance of Angiosperms is between 141 and 154 Ma (Bell et al. 2010). Although molecular dating methods tend to overestimate divergence times (Rodriguez-Trelles et al. 2002), this age estimate obviously seems an indication of the presence of bias and may imply that the dating of other nodes may also be skewed. Moreover, the long branch between the stem node and the Ochnaceae crown node reflects some 30 million years of absent branching events, either caused by an actual lack of divergences or by extinction events. This is a fundamental problem with no obvious solutions (Givnish and Renner 2004) hindering

the reconstruction of the biogeographic history of the family with confidence, i.e. with high support values, especially to satisfy our interest in the ancestral area of the family. As such, the distribution data of the outgroup was not relevant in our analyses because of the uncertain affiliations and unknown events that may have occurred on the long branch between the stem and crown group of Ochnaceae.

Nevertheless, there is strong support for the hypothesis that Ochnaceae originated in America (A, Fig. 3). All backbone nodes of the phylogenetic tree have their inferred origin in the Neotropics, strongly suggesting this is the ancestral area of the family. Early dispersal to Africa led to the development of Testuleeae, around 69 Ma, in the late Cretaceous. Later on, other dispersal events to Africa and beyond took place (discussed above).

As for the questions related to the dispersal routes Ochnaceae used to move between continents, one hypothesis is that the Ochnaceae disjunction is the result of a boreotropical migration. This would imply that Ochnaceae were part of a boreotropical flora present in the Northern Hemisphere during periods when climate supported tropical forest in the late Cretaceous and early Palaeogene. During that time, the global climate was warm (Zachos et al. 2001) and tropical vegetation was present at much higher latitudes than today (Wolfe 1975; Tiffney 1985). The cooling of the climate during the late Eocene (Zachos et al. 2001) caused the tropical taxa to move south toward the equator or to go extinct. It has been suggested that this flora was replaced by a frost-tolerant temperate flora around 40 Ma (Wolfe 1975, 1980; Morley 2000). Being frost-intolerant plants and knowing that phylogenetic biome shifts are rare (Crisp et al. 2009), it is more likely that Ochnaceae would have retained their ancestral ecological preferences and receded into the southern Hemisphere toward more suitable, warm habitats. Therefore, the absence of specific Ochnaceae fossil evidence from the boreotropical region does not preclude the assumption that this family was once part of that flora.

The early divergence events in crown group Ochnaceae fall in a period around the K-T boundary (66 Mya), suggesting that most of the Cretaceous representatives of Ochnaceae had gone extinct during the mass extinction event and that all of the crown group taxa originated thereafter. Such a scenario would also explain the long branch between stem and crown group Ochnaceae.

For American organisms, the North Atlantic Land Bridge (NALB) has been postulated as a potential dispersal route towards the Old World. Examples, based on molecular and fossil data, to support that the NALB may have been available to many angiosperm plants are found, for example, in Annonaceae and Rhamnaceae (Richardson et al. 2004), Malpighiaceae (Davis et al. 2002), Lauraceae (Chanderbali et al. 2001), and Rubiaceae (Smedmark et al. 2010). This route has also been viewed as a key to the understanding of disjunct distribution patterns between eastern Asian and eastern North American taxa (Tiffney 1985).

For Ochnaceae, dispersal from America to Africa should have started with migration from northern South America to North America via the oceanic Caribbean plate, the proto Greater Antilles (early Eocene, about 57-48 Ma) and/or GAARlandia (the Greater Antilles and a now submerged Aves Ridge connecting Cuba, Hispanolia and Puerto Rico to mainland South America) that was available during the Eocene-Oligocene (Graham 2003a, b; Ali 2012). After passing the NALB, migration from Europe into Africa may have followed the Tethyan dispersal route, which existed until the Late Eocene (Morley 2003).

An alternative explanation for the migration of Ochnaceae to be explored is long distance dispersal (LDD) from South America directly to Africa across the Atlantic, or vice versa (e.g. (Givnish and Renner 2004; Renner 2004; De Queiroz 2005). During the Tertiary, Africa and South America were not connected by land. However, a series of islands may have acted as stepping-stones throughout the late Cretaceous and the beginning of the Tertiary (Parrish 1993; Morley 2003). Those land connections were possibly located in the region of the Walvis Ridge (a stretch from Angola to Brazil/Rio-Grande), and the Sierra Leone Ridges (Morley 2003). This would have allowed proximity of land masses between the east coast of South America and the west coast of Africa. Evidence of plant as well as vertebrate dispersal across the Atlantic by wind and sea currents was reported in Renner (2004). She states that vertebrates (rodents and monkeys) must have travelled between continents and it is not excluded that Ochnaceae could have rafted along as well. LDD is thought to be an event of rare occurrence (Nathan 2006) predictable if knowledge of dispersal mode (wind, birds, oceanic drift or rafting) and other factors such as the organism's natural environment and biology are known (Gillespie et al. 2012). Ochnaceae are probably dispersed by wind or birds (Amaral and Bittrich 2014) but, unfortunately, evidence on the exact dispersal vector (wind or bird type) is not available making it difficult to state that LDD across the Atlantic has played a role in the distribution of Ochnaceae. Due to these limitations and our current data, LDD across the Atlantic is weakly tenable as a hypothesis to explain the disjunct distribution of Ochnaceae.

By consequence, we postulate that Ochnaceae colonized the Old world through the NALB. This route may have served as a migration route of Ochnaceae lineages at different times. *Testulea*, and *Fleurydora* independently dispersed into Africa and could have used the NALB, which according to dating analysis was available for all two (late Cretaceous to early Oligocene).

This same dispersal route might have been taken by the Medusagynoideae to arrive in the Seychelles Island, which is estimated to have originated around 85 Mya (Braithwaite 1984). Time estimates suggest that Medusagynoideae originated in the early Paleocene. The ancestral lineages of modern Medusagynoideae could have migrated, along with

the boreotropical flora, between North America and Eurasia via the NABL or the Bering Land Bridge (BLB) connecting Asia and North America (Tiffney and Manchester 2001). During the cooling period in the late Eocene, the ancestral lineages of Medusagynoideae could have moved toward south Asia as a response to the cooling. It is more likely, that these ancestral lineages migrated from South Asia to the Seychelles via the collision of Indian Plate with Asia, which happened around 50-39 Ma (Morley 2003). The separation of India and the Seychelles was completed around 62 Ma (Collier et al. 2008). This suggests that few dispersal events happened to explain the current occurrence of the Medusagynoideae in the Seychelles. The presence of islands such as Maldives, Chagos archipelago and Saint Brandon between India and Seychelles (Warren et al. 2010) could have facilitated dispersal of Medusagynoideae between India and the Seychelles.

Finally, it is noteworthy to mention the amphi-pacific relationships observed in the Ochninae and Sauvagesieae clades. Within Sauvagesieae, our molecular dating analyses inferred the age of the split between the Asian species (*Schuurmansi*, *Schuurmansiella*, *Sauvagesia* and *Euthemis*) and their neotropical sister (*Tyleria*) in the Early Miocene, around 21.4 Ma (Fig. 2, node 8). This amphi-pacific split is too young and could not result from the disruption of the boreotropical ranges during the mid/late Eocene (Wolfe 1975; Tiffney 1985). However, one possible explanation for this disjunctive distribution is LDD involving the BLB. Based on marine data, this route was available from at least the early Paleogene (c. 60 Ma) until its closure between 7.4 and 4.8 Ma. However, Tiffney and Manchester (2001) doubt that the BLB was available as a migration route for tropical taxa. It may have been located too far north, between 69° and 75°, where a long period of winter darkness would have posed a barrier for evergreen angiosperms to cross. Moreover, fossil evidence showing that tropical taxa have existed in the region is scarce and questioned (Tiffney and Manchester 2001). A second alternative explanation is LDD dispersal through the Pacific Ocean. Examples of clades that display amphi-pacific distribution are reported by (Givnish and Renner 2004; Qian and Ricklefs 2004; Davis et al. 2005). The red drupes of *Euthemis* are probably ornithochorous whereas the seeds in capsular fruits of *Schuurmansi*, *Schuurmansiella*, and *Sauvagesia* are probably dispersed by wind. The latter may thus allow LDD, although some seeds can be dispersed by mechanisms for which they do not show any adaptation (Higgins et al. 2003). Still, LDD seems a likely hypothesis explaining the distribution pattern within Sauvagesieae.

LDD might also be involved in shaping the observed distribution pattern of Ochninae (node 13). Time estimates suggest that the Ochninae diverged in the mid to late Miocene. Although the Ochninae backbone is poorly resolved, most likely explanation for the occurrence of a Neotropical clade *Ouratea* (node 16) in an otherwise African-Asian subtribe is dispersal back to America. Here, again, the NALB seems to have been available as a conduit for the migration of the ancestor of *Ouratea* in the mid-Miocene

since their MRCA originated in Africa around 15 Ma (95% HPD: 11–20.6 Ma). The NALB was hypothesized to have facilitated range expansion of some Malpighiaceae lineages with Miocene divergence times (Davis et al. 2002). Of course, long distance dispersal right across the southern Atlantic Ocean cannot be ruled out. Finally, subsequent oceanic dispersals out of Africa to Madagascar, and India to Southeast Asia occurred and explained the distribution patterns of *Brackenridgea*, *Campylospermum* and *Ochna*. During the late Miocene, Comoros might have facilitated dispersals between Madagascar and Africa, and via Mascarene and Seychelle islands for dispersal between Madagascar and India to Southeast Asia (Warren et al. 2010; Buerki et al. 2013).

6.5 Conclusion

Our study indicates that Ochnaceae originated in the Neotropics and started to expand their range to the Palaeotropics during the late Cretaceous and early Paleocene. Its present-day distribution pattern is likely to be mainly the result of boreotropical migration through the NALB. Our study on Ochnaceae adds to the growing body of evidence for tropical plant groups using the NABL to spread between Old and New World continents during post-Gondwanan times. Further, Ochnaceae genera are generally restricted to a particular continent. The distribution pattern of most of its extant taxa is unlikely to have been influenced by transatlantic long-distance dispersal. However, the distribution patterns observed for the Ochninae and Sauvagesieae, although their divergence time estimations may not be accurate because of the weak phylogenetic support, would be best explained by LDD. Finally, suggestions to improve our dating results may come from the use of different dating analyses, choice of calibration point, improved taxon and gene sampling, and most importantly a proper Ochnaceae fossil.

Chapter 7

General discussion

7.1 Introduction

The natural world and our human society are often considered as opposing entities with competing claims for natural resources (Giller et al. 2008). However, they are heavily intertwined, evolving side by side since they coexist on the same planet, Earth. Hence, they should better be considered as parallel and/or complementary worlds and it is important, also for our own well-being, to know what nature encompasses and may have to offer both in direct benefits (medicine and food, resistance genes, building materials, etc.) as well as indirect ones (mind-relaxing experiences, carbon storage, etc.).

Systematists have set out to understand the complexity of our natural world. Their mission is to discover, describe and inventory species diversity (Daly et al. 2012), to increase our knowledge of earth's species (Pitman and Jørgensen 2002; Chapman 2009; Stuart et al. 2010; Mora et al. 2011), to understand the origin of the biogeographic and evolutionary patterns of this diversity (Sanmartín and Ronquist 2004; Buerki et al. 2013), to identify biodiversity hotspot (Myers et al. 2000; Küper et al. 2004; Joppa et al. 2010), and to define specific approaches to setting conservation priorities (Mittermeier et al. 1998; Myers et al. 2000; Brooks et al. 2006). These goals have entered various work programmes of the Convention on Biological Diversity (<http://www.cbd.int>) and are pivotal for the realisation of the goals of the United Nations Decade on Biodiversity 2011-2020 (<http://www.cbd.int/2011-2020>).

Within this broader framework, we may ask what this thesis contributes in terms of species discovery, description and our understanding of nature. Below, this is discussed for the different components of the thesis, along with suggestions for further improvement and extension.

7.2 Molecular phylogeny of the pantropical family Ochnaceae

When aiming at understanding how earth's biodiversity has evolved, we need to unravel phylogenetic relationships; a huge task indeed. A phylogenetic tree represents a hypothesis about the relationships between taxa that diversified at a specific time as a result of a historical event. Since theoretically the correctness of such a hypothesis cannot be tested using experiments (see (Cleland 2001) we need to obtain as much data as possible from our objects, species, clades, individuals, etc. to find out what is their most likely diversification pattern. The available information is fed into phylogenetic analyses and the results are graphically represented in a phylogenetic tree. The likeliness of the correctness of the hypotheses about the evolution within the group concerned is then obtained. By providing our hypothesis on the evolution within the Ochnaceae, we thus provide a small contribution that adds up to our knowledge about the origin of the present-day natural diversity.

The family Ochnaceae belongs to the order Malpighiales, which is one of the most diverse orders among the Rosids. It includes a wide range of ecological diversity such as the odd aquatic family Podostemaceae, holoparasites (Rafflesiaceae) and cactus-like succulent plants (within Euphorbiaceae). At the onset of this study, the molecular phylogenetic relationships among the families of Malpighiales, including those of the Ochnaceae, were not well supported (APG III 2009). To date, there seems to be good support for the position of Ochnaceae being sister to a clade including amongst others the Clusiaceae (=Guttiferae) and Hypericaceae (Xi et al. 2012). The relationships within Ochnaceae were equally unresolved or even unknown, which formed the cause and justification for our choice to study this group.

A first prerequisite to resolve phylogenetic relationships at a given taxonomic level is to provide a sufficiently large taxon sampling for that group. We provided for the first time a comprehensive taxon sampling of Ochnaceae, covering nearly 94% of the genera to resolve relationships and circumscription of Ochnaceae which consists of three subfamilies: Medusagynoideae Reveal, Quiinoideae Luerss. and Ochnoideae Burnett. Species-level relationships and diversification patterns are still in need of further investigations since only 14% of the species were included.

Second, the choice of appropriate DNA markers is crucial for phylogenetic inference. At the onset of this study, the chloroplast *trnL-F* region had proven to be an appropriate marker in the molecular phylogenetic study of Quiinaceae (Schneider et al. 2006), and we decided to use this marker along with several others. This resulted in the construction of two data sets. The first one was produced in cooperation with the Senckenberg Research Institute at Frankfurt (Schneider et al. 2014) and contained sequence data for four plastid markers (*matK*, *ndhF*, *rbcL*, *trnL-F*) and part of the nuclear ribosomal DNA cistron (including ITS1, 5.8S, ITS2). It contains 79 terminal taxa and three representatives of the closely related clusioid clade, which were chosen as outgroups. The resulting phylogeny was presented in Chapter 4. The second data set had a taxon sampling focussing on Ochninae and was composed of three plastid gene regions (*matK*, *rbcL* and *trnL-F*). It had a total of 87 terminal taxa, including two relevant outgroups from the Malpighiaceae. Results of the analysis of this set were presented in Chapter 5.

Regarding the choice of markers, our analyses based on combined chloroplast and nuclear markers showed better resolution than those based on chloroplast markers alone. This is not surprising because, due to the higher substitution rate, ITS adds a large number of variable sites and is thus better suited to provide resolution at lower taxonomic levels. However, some chloroplast genes, such as *atpB*, *matK*, *ndhF* and *ycf1*, also contain high levels of genetic variation capable of resolving intergeneric as well as inter-specific relationships (Neubig et al. 2009; Soltis et al. 2011). Unfortunately, using

matK and *rbcL* failed to produce strong support values for clades within the Ochnaceae (chapter 5) as the variability of those markers is insufficient. Furthermore, the difficulty in resolving relationships within Ochnaceae might be attributed to a relatively recent and explosive radiation given the age estimates and species-richness of several of its clades. Unfortunately, not all commonly used angiosperm genetic markers are able to resolve such radiation. However, genomic-based approaches have proved to yield significant resolution in both recent and ancient rapid radiations (Parks et al. 2009; Xi et al. 2012; Nadeau et al. 2013). Within Malpighiales, Xi et al. (2012) sampled several plastid genes from *Medusagyne* (71), *Ouratea* (79) and *Quiina* (52) with plastid genome coverage of 89, 93 and 73% respectively. These data already provide a variable repertoire of genomic sequences that might well be able to further refine the phylogenetic tree and/or provide stronger support of some of the clades within Ochnaceae. This will require generating a huge amount of genomic sequences, which can nowadays be delivered fast and at comparatively low cost using next-generation sequencing technologies (Davey et al. 2011; Stull et al. 2013).

7.2.1 Phylogeny of the subtribe Ochninae

One of the research questions of the current study was to clarify the phylogenetic position of the genus *Campylospermum* within the Ochnaceae. In chapter 4 and 5 we presented the results of the molecular phylogenetic analyses, which have positioned *Campylospermum*, along with the genera *Brackenridgea*, *Idertia*, *Ochna*, *Ouratea* and *Rhabdophyllum*, in the subfamily Ochnoideae, tribe Ochneae, subtribe Ochninae. The six genera resolved into six different clades, though with weak support values. This is probably due to a low level of DNA sequence divergence of the markers we used, or for reasons discussed further in this section. The trees generated in chapter 4 and 5 were based on concatenation methods. All genes and data partitions were combined into single supermatrix prior to the analyses. This was done in order to obtain a total evidence tree of the Ochnaceae phylogeny, as advocated by (Kluge 1989; Kluge 2004). Studies using this procedure have proved to perform well because they resolve shallow and deep branches in the tree (Chen and Li ; Rokas et al. 2003). However, the correctness of concatenating all types of DNA sequences has been questioned, especially those from rapidly divergent clades (Kubatko and Degnan 2007). For instance, Degnan and Rosenberg (2006) have shown that for any species tree of five or more taxa, there exist branch lengths in species trees for which gene trees that do not concord the species tree are more common than gene trees matching the species tree. It is obvious that, as commented by Edwards (2009), gene trees will always differ from one another, even when topologically congruent. Phylogenetic analysis of concatenated sequences is thus more likely to mislead inference of species relationships (Kubatko and Degnan 2007). The cause of conflict between gene trees and the species tree is

known to molecular systematics and well-reviewed, for example by (Maddison 1997; Degnan and Rosenberg 2009). One of the causes, which could be related to our data, is deep coalescence. Indeed, the uncertain relationships among the Ochninae and the short branches observed in the phylogenetic tree could be viewed as a problem of deep coalescence, also called incomplete lineage sorting (Maddison 1997; Nichols 2001). Deep coalescence is the failure of gene copies to coalesce (when travelling backwards in time) within the lifetime of a species, but instead coalesce in an ancestral species (Pamilo and Nei 1988; Maddison 1997; Nichols 2001). Evidence for deep coalescent is very common in many phylogenetic trees, particularly those depicting sufficiently short branch lengths (Jennings and Edwards 2005; Pons et al. 2006; Hobolth et al. 2007; Xi et al. 2013).

This highlights the need to account for gene tree/species tree conflicts when reconstructing the Ochnaceae phylogeny. As such, coalescence based phylogeny, as an alternative to concatenation methods, could represent an option for further study. Models to estimate phylogenetic trees under coalescence have emerged (Liu and Pearl 2007; Liu et al. 2009; Xi et al. 2014) and have broad attention from the systematic community (Edwards 2009; Wu et al. 2013; Springer and Gatesy 2014). In general, the phylogenetic tree of species contains smaller gene trees within its branches (Maddison 1997), and, as a consequence, phylogenetic reconstruction of species based on multiple genes should incorporate the probability distribution of each gene tree given the phylogeny of the species (Maddison and Knowles 2006; Liu and Pearl 2007; Liu 2008; Degnan and Rosenberg 2009; Kubatko et al. 2009). Thus, for future investigations in the Ochninae phylogeny it might be necessary to combine all of these elements to arrive at a good estimate of its phylogenetic tree.

7.2.2 Biogeography of Ochnaceae

Estimating the divergence time of a taxon may offer explanations from the geological or palaeoclimatological domain to uncover and understand the patterns of diversification within that group. This requires a well-supported phylogenetic tree, as well as inferences of ancestral areas and assumptions on the direction of movement of taxa (Smith 2009; Smedmark et al. 2010; Bartish et al. 2011; Li et al. 2011; Smedmark et al. 2014).

Species diversification

Our molecular age estimates for Ochnaceae have shown that early diverging branches, *Testulea* and *Medusagyne*, respectively, have an age of around 69–64 Ma, corresponding to the late Cretaceous-early Paleocene. Most of the genera have diverged in the Eocene and Oligocene or late Miocene. The genera as well as species richness are not evenly distributed across the various main clades of the family. *Medusagynoideae* is a monotypic subfamily, thus includes a single species. The Quiinoideae include 55 species in four

genera, whereas the Ochnoideae comprise about 500 species in 27 genera. The latter does not only include the three most species-rich genera *Campylospermum* Tiegh. (c. 50 spp.), *Ochna* L. (c. 80 spp.) and *Ouratea* Aubl. (c. 200 spp.) but also the monogeneric tribe Testuleeae, two subtribes Lophirinae, Elvasiinae and one monotypic genus *Fleurydora*. Such unequal distribution of genera and species over clades has generally been explained by a combination of continental drift, dispersal events, climatic changes, geological activity as well as diversification processes (speciation and extinction rate) in time and space (Plana 2004; Ricklefs 2004; Alfaro et al. 2009; Baker and Couvreur 2013). Within Burmanniaceae (Merckx et al. 2008), Brassicaceae (Couvreur et al. 2010), Proteaceae (Sauquet et al. 2009), and Rosid clades (Wang et al. 2009) species diversification rates were hypothesized to first have had an early and rapid increase followed by a decrease. In palms however, show increased diversification rates in recent times (Baker and Couvreur 2013), whereas within Annonaceae clades, a constant rate model of diversification was suggested (Couvreur et al. 2011). This makes us wonder what rate changes took place during the evolutionary history of the Ochnaceae. It was postulated that the diversification rate in Medusagynoideae has slowed down (Xi et al. 2012). In contrast, species richness in Ochnoideae may be attributed to an acceleration of the diversification rate. However, for a full understanding of their phylogeny, it seems worth to investigate whether the diversification rate within this subfamily steadily increased, or whether there were diversification peak moments. A stepwise approach based on the Akaike Information Criterion (AIC) implemented in MEDUSA (Alfaro et al. 2009) could be used to detect such shifts of diversification rate. MEDUSA is a comparative method that integrates phylogenetic information about the timing of splits along the backbone of the tree with taxonomic richness data to estimate rates of speciation and extinction and it is suited for incompletely resolved phylogenies (Alfaro et al. 2009). An analysis of the patterns of Ochnaceae diversification using MEDUSA will require the integration of the approximate number of accepted species for each subfamily and genus with the time-calibrated tree. This analysis will generate the Ochnaceae diversity tree in which shifts in birth (speciation) and death (extinction) rates would be identified. Investigating the changes in tempo of Ochnaceae diversification would provide a framework for assessing hypothetical explanations of Ochnaceae radiation and help to understand the drivers behind speciation processes within this family and its clades.

Ancestral area reconstruction

Chapter 6 provides strong support for the hypothesis that Ochnaceae originated in South America. The program BBM was preferred instead of S-DIVA, and used trees generated in BEAST. Our reconstructed ancestral area analysis has recovered 28 dispersal and 14 vicariance events using BBM implemented in RASP. One could question whether similar figures could be reached using the maximum likelihood framework Lagrange (Ree et al.

2005; Ree and Smith 2008) which, in addition to the geographic areas occupied by the extant taxa, defines area ranges on the basis of adjacency or connection of these areas at different time periods. With Lagrange, a connection can be modeled as a function describing the probability of dispersal success between two areas through time (Ree et al. 2005). As such, two connectivity scenarios could be considered. The first would require a probability function of allowing any movement between areas at any time. The second would constrain movement between North America and Europe across the NALB after the Eocene, 34 Ma (Tiffney and Manchester 2001). The analysis would estimate the probability of successful dispersal between areas and allow to not invoke unsuccessful dispersal scenarios.

- Biogeography of *Campylospermum* and its centre of diversity in tropical Africa

The continental African species of the genus *Campylospermum* occur from Senegal to Angola and from Ethiopia to Zambia (Fig. 1), with highest diversities in regions covered by evergreen forest. They are distributed within three biogeographic areas, the Congolian region, the Sudanian region and the Zambezian region, all sensu (Linder et al. 2012). Widespread species such as *C. reticulatum* and *C. vogelii* are found in all three biogeographic regions, but most are restricted to only one. No species is restricted to the Sudanian region; the occurrences there all relate to outlier populations of more drought-resistant species that have their main distribution centre within the Congolian region. Relatively few species, such as *C. bukobense*, *C. lunzuensis* and *C. plicatum*, are distributed across the Congolian and Zambezian region. Five species (*C. andongensis*, *C. lutambensis*, *C. sacleuxii*, *C. scheffleri*, *C. warneckei*) are endemic to the Zambezian region while the majority (38 species, about 81%) of *Campylospermum* species is restricted to the Congolian region. The latter is subdivided into three subregions: Guinea, Congo and Shaba. Eighteen species are restricted to the Congo subregion while three species (*C. amplexens*, *C. congestum* and *C. schoenleinianum*) are endemic to the Guinea subregion. No endemics are known to occur in the Shaba subregion. Species such as *C. calanthum*, *C. duparquetianum*, *C. dybovskii*, *C. elongatum*, *C. flavum* and *C. sulcatum* are more widely distributed and found in both the Guinea and Congo subregions.

The highest concentration of political endemics (species occurring within the borders of a single country) of *Campylospermum* is found in Gabon (four species: *C. gabonensis*, *C. klainei*, *C. louisii*, *C. occidentalis*). *C. nutans* is an endemic of Sao Tomé and Principe while *C. claessensii* is endemic to the Democratic Republic of the Congo. In other words, all endemic *Campylospermum* are only known from the Congolian region. Striking is the absence of species endemic to Cameroon, because that country normally has a high percentage of endemics in other plant groups (Cheek et al. 2011). Besides the political endemics, a total of eleven other continental African *Campylospermum* species have a restricted distribution. Eight of them are found in the Congolian region along the coast

of the Atlantic Ocean from the area around the border between Nigeria and Cameroun to Angola (Cabinda) and three from the Zambezian region, mainly from the Eastern Arc mountain range in Kenya and Tanzania (Fig. 2).

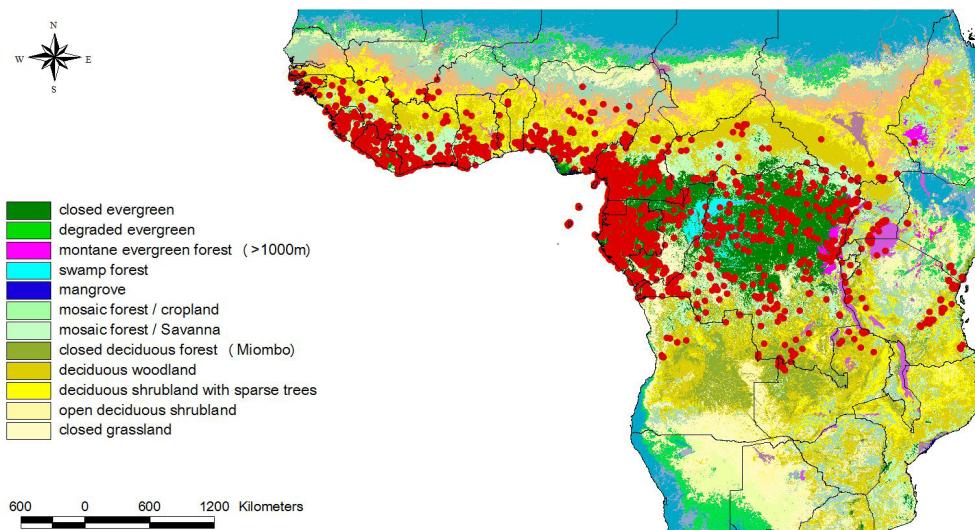

Figure 1. Distribution map of all herbarium specimen records of continental African *Campylospermum* species, overlaid with the vegetation cover map of Africa.

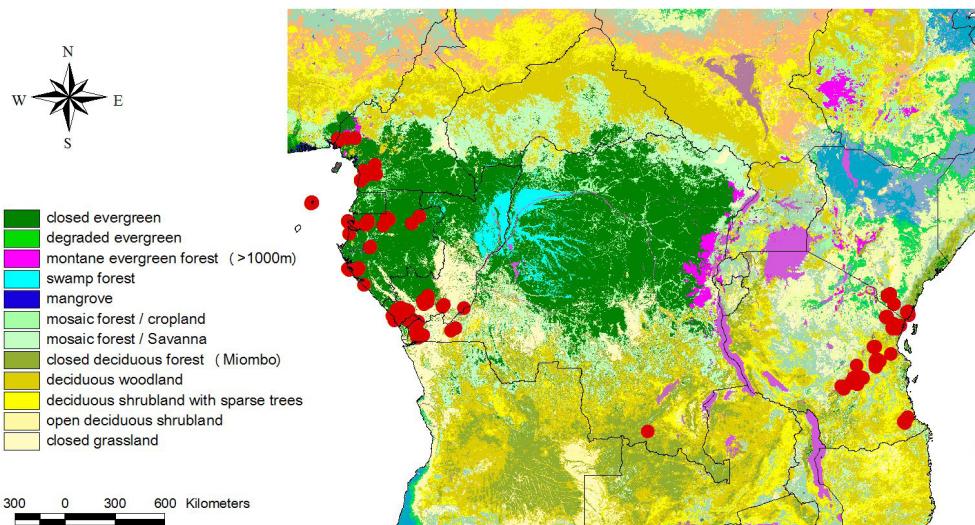

Figure 2. As Figure 1, but restricted to all political endemics and species with a restricted distribution.

From the distribution of the genus *Campylospermum* some general facts can be drawn about its centre of diversity, although the pattern could be affected by possible bias related to the rarity of species, number of collection trips, and collecting strategies of botanists (Haripersaud 2009). Indeed, it is known that estimating species richness is statistically

challenging because it is almost impossible to know how many individuals or samples should be collected to cover all species that are present (Gotelli and Colwell 2001). For the fact that many species may remain undiscovered to any survey of diversity, methods of estimating species diversity have incorporated species accumulation measurements, rarefactions, species richness and density to correct these biases (Chao et al. 2009) and tend to work well when dealing with herbarium specimens (Droissart et al. 2012).

Further analyses of the patterns of *Campylospermum* diversity in which these biases are taken into account are needed so that proper reliable areas of diversity and endemism are determined. Nevertheless, the three biogeographic regions show a clear patterning in both species richness and endemism. Our study provides additional support for the Congolian as being a region of high-level diversity and endemics (Linder 2001). This biogeographic region approximately corresponds to the Guineo-Congolian phytocchorion delimited by White (1979). The majority of species as well as the majority of endemic species are distributed in the Congo subregion. Even more specific, the actual centre is situated in the Lower Guinea phytoregion as defined by White (1979), which covers the area from south-eastern Nigeria to northern Angola, and as such this area should be regarded as the main centre of diversity of *Campylospermum*. Many other genera having species practically confined to rain forest habitats have their centre of diversity in the same area, for instance, *Isolona* Engl. and *Monodora* Dunal (Couvreur et al. 2008); *Anthonotha* P. Beauv and *Isomacrolobium* Aubrév. & Pellegr. (Breteler 2010; Frans J. Breteler 2011); *Octoknema* Pierre (Gosline and Malécot 2011); *Dacryodes* Vahl (Onana 2008); *Heckeldora* Pierre (Wilde 2007) and *Trichoscypha* Hook.f. (Breteler 2001, 2004). Moreover, this region has some endemic genera such as *Aucumea* Pierre (Burseraceae), *Lecomtedoxa* (Pierre ex. Engl.) Dubard (Sapotaceae) and *Testulea* Pellegr. (Ochnaceae). It is worthy to note that, within the Congo subregion, Gabon is the most diverse country because of the exclusively occurrence of endemic *Campylospermum* species (Fig: 2). The high diversity of this subregion might be explained by its rather heterogeneous hilly topography and comparatively high rainfall. A second explanation might come from historical factors. In the evolutionary history of the tropical forest of Africa, during the Pleistocene, the various glacial periods may have led to forest fragmentation, isolation and subsequent diversification of its inhabitants (Bush 1994). It is argued that signatures of these historical events are captured in areas identified as potential refugia (Sosef 1994; Robbrecht 1996). It is also suggested that these refugia acted as reservoirs of ancient diversity during glacial periods (Evans et al. 2004), while many species went extinct elsewhere. These refugia may also have played a role in shaping genetic diversity of other organisms, such as the gorilla (Anthony et al. 2007) and montane birds (Bowie et al. 2006). In Gabon, potential refugia are likely located in upland areas such as Massif du Chaillu, Mont Doudou (southern Gabon) and Monts de Cristal in the north-western Gabon and adjacent Equatorial Guinea (Sosef 1994; Maley 1996). The distribution pattern of most endemic *Campylospermum* species indeed follows these areas.

The second centre of *Campylospermum* diversity is found in Guinea subregion, separated from the Congo by the boundary placed at the Sanaga River (Cameroon) to the east of Mount Cameroon (Linder et al. 2012). Support for this boundary comes from studies on vascular plants (Lawson 1996), primates (Anthony et al. 2007) and mammals (Kreft and Jetz 2010). Three species are strictly endemic to Guinea: *C. amplectens*, *C. congestum* and *C. schoenleinianum*. The rain forest of the Guinea subregion is divided into two blocks by the so-called Dahomey Gap, a dry area covering Benin, Togo and eastern of Ghana. In our study, the Dahomey Gap is evident from the distribution of *C. calanthum*, *C. laxiflorum*, *C. reticulatum*, *C. sulcatum* and *C. vogelii*, while the species *C. flavum* and *C. glaberriuum* do have some records from within this dryer zone.

The third centre of diversity is found in the Zambezian region, which includes a total of eight species of *Campylospermum*, five of which are strictly endemic. The distribution of these endemic species is confined to coastal and montane East Africa rain forests, except for the interior species *C. andongense*. They were all assessed as being of Least Concern according to the IUCN criteria (Chapter 3), but are located in the two known hotspots from East Africa (Küper et al. 2004; Mittermeier 2005). Thus, knowing that these hotspots were identified based on their high diversity combined with a high threat level (Burgess and Clarke 2000), one may expect this status to change in the near future.

7.2.3 Taxonomic revision of the continental African species of *Campylospermum*

In our revision of the continental African species we have recognized 47 species with one species comprising two subspecies. Farrons sectional arrangement based on embryo type was not recognized since different types of embryos appeared to be present within a section (Chapter 3).

Quite a number of new species have been recognized lately (Sosef et al. 2007; Bissiengou and Sosef 2008; Bissiengou et al. 2013), some of which were based on rather recently collected herbarium specimens. Because of that, it is likely to assume that more new species remain to be discovered. Although herbaria generally act as the major facilities for species discovery (Bebber et al. 2010), we expect such species to be discovered from new field work since the collections from almost all relevant herbaria have been studied for the present revision of *Campylopermum*.

There are likely to be $\sim 5 \pm 3$ million species on Earth (Costello et al. 2013). Estimates of the number of described species vary between 1.4 (Pennisi 2003) and 1.9 million (Chapman 2009). Approximately 390,000 species of plants are thought to occur on our planet, of which about 310,000 have been described (Chapman 2009). Thus, there are still many more species out there that await their discovery and description. As long as these species remain unknown to science, their extinction will not be notified. This

should not be taken lightly, firstly because even unknown species may already provide valuable resources for our human society. For example, even the flower parts and nectar of many plant listed in (Lim 2014) provide conventional or functional food and may also serve as a source of food colorant, additive or neutraceuticals. If unknown species go extinct, we will not be able to know what resources they could have provided. Secondly, species serve as a measurement of biodiversity. They help to distinguish different sorts of habitats and identify areas that are taxonomically under-explored or form a biodiversity hotspot under threat. In Gabon, such areas have been identified by (Sosef et al. 2006; Walters et al. 2011; Lachenaud et al. 2013). Moreover, species are part of an ecosystem, interacting with other living organisms and thus creating interdependencies. The survival of one species may well depend on the presence of one or several others. Members of the Poales for example dominate many terrestrial and aquatic ecosystem (Bouchenak-Khelladi et al. 2014). They have influenced the evolution of hominids, mammals and provide the basis for most human diets (Janis 1993; Bouchenak-Khelladi et al. 2009; Givnish et al. 2010). When a larger number of species go extinct, it will cause disturbance or even the collapse of the entire ecosystem, similar to the collapse of coastal ecosystems due to overfishing (Jackson et al. 2001). Furthermore, species discovery is also important in the light of conservation. The more complete our knowledge is about which species occur in a certain area, the more effective conservation measures will be. Gabon has created 13 National Parks (NPs), representing 11% of its landmass, for conservation (Sosef et al. 2006). Unfortunately, full inventories or even estimates of species richness within these parks are often non-existing for many groups of organisms including plants. The danger of this situation is that, especially in periods of economic crisis, NPs could have their limits reduced because of ignorance about their actual value. The Sierra San Pedro Màrtir National Park in California (Mexico) faced some ambiguity in the park boundaries. About 3000 ha of its landmass, which encompasses mixed conifer stands of high commercial value, was excluded from the park. However, because of habitat loss species occurring within the park boundaries can become threatened or even go extinct (Bojórquez-Tapia et al. 2004). Finally, some claim that the full discovery of Earths species is achievable within 50 years depending on the focus of all taxonomists worldwide and the extinction rate (Costello et al. 2013). Therefore, by unravelling the taxonomy of *Campylospermum*, this study also contributes to this general goal.

- Diagnostic characters

In general, characteristics of the leaf shape and venation, and inflorescence structure are used to tell the species of *Campylospermum* apart. In contrast to many other plant groups, flowers are fairly uniform and do not provide many diagnostic features. Sargent (2004) suggested that flower morphology plays a key role in angiosperm speciation and is correlated with an increase of the diversification rate driven by selection through

pollinator specialization. If such is the case, then floral morphology in *Campylospermum* may not be tightly associated with the formation of new species indicating the absence of a tight relationship with pollinators. It is known, however, that selection by specialized pollinator alone may not be consistent and strong enough to drive adaptive divergence of floral forms (Waser 1998).

- Species identification using DNA barcoding

Species identification and description is generally still achieved through comprehensive taxonomic work (Will and Rubinoff 2004). Within *Campylospermum*, species delimitation was difficult particularly for *C. laxiflorum*, *C. reticulatum* and *C. vogelii* which are considered here as species complexes. The latter two species were previously subdivided into varieties that are not accepted here because there were no clear distinctions between them. All three are widespread and common species, thus occurring in different environmental conditions where they may show slightly different morphological features, rendering the delimitation of these species extremely complicated. Species delimitation can also be addressed by applying phylogeography or population genetics, as is demonstrated by (Dauby et al. 2010; Duminil et al. 2010; Ley and Hardy 2010; Duminil et al. 2012). DNA barcodes rapidly gain interest as an alternative to facilitate the process of species delimitation (Hebert et al. 2004; Barrett and Hebert 2005; Hajibabaei et al. 2006; Smith et al. 2006). A DNA barcode is a short DNA sequence from a standardized part of a specific gene region (Hebert, Cywinska, et al. 2003; Kress et al. 2005). This involves choosing one or a few standard loci that can be sequenced routinely and reliably in a wide diversity of sample sets (Hollingsworth 2011). For animal groups, the mitochondrial gene CO1 is selected as the universal barcode (Hebert, Ratnasingham, et al. 2003). However, the low substitution rate of this mitochondrial DNA hampers its use in plants. Hence, the use of the 2-locus combination of *rbcL* and *matK* (CBOL Plant Working Group 2009) and additional barcodes such as the internal transcribed spacer ITS, *trnH-psbA*, *atpF-atpH*, *psbK-psbI* intron and *trnL* intron are recommended for plant (Kress and Erickson 2007; Hollingsworth 2011; Hollingsworth et al. 2011). For the highly variable species *C. laxiflorum*, *C. reticulatum* and *C. vogelii* DNA barcode sequences could be generated at relatively low cost (Hajibabaei et al. 2005; Ivanova et al. 2006). This should involve the sampling of as many individuals as possible per species, especially from different geographical locations. The resulting DNA barcode sequences might then assist to sort specimens into genetically distinct taxonomic groups (Smith et al. 2005). Specimens that thus do not fit the DNA barcode of a taxonomic species would be subjected to a thorough morphological study. When differences can be detected, one could proceed in describing a new species. However, when a DNA barcode difference cannot be backed up by morphology, this might indicate the presence of a cryptic species and further study is advisable. In conclusion, the use of DNA barcodes is highly advisable for taxonomic studies on species complexes.

- Habit and architecture

Species of *Campylospermum* are small or occasionally larger trees. The majority of them are branched, but some are unbranched (monocaulous). While the inflorescence is generally terminal, they are mostly axillary in monocaulous species. Field observations on two species with axillary inflorescences, the monocaulous *C. elongatum* showed that after fruiting, the old and formerly pendulous inflorescence axis curves up to form a leafy twig. This might indicate that the apparent axillary inflorescences in fact represent terminal inflorescences on axillary twigs. This will need further verification.

Some species of *Campylospermum* act as 'litter-bin' species. Their broader spatulate and cordate leaf bases allow them to collect plant debris fallen from the canopy while often roots are formed which tap into the collected litter. Most of these species are monocaulous (*C. amplexens*, *C. duparquetianum*, *C. elongatum*, *C. klainei*, *C. mannii* and *C. subcordatum*) but some have a normal branched trunk (*C. auriculatum*, *C. oliveri* and *C. schoenleinianum*). While the first carry their leaves crowded at the top of the stem, the latter have relatively well-spaced internodes and litter is collected by only a part of the individuals.

The monocaulous litter-bin species are slow-growing plants; the average growth in height is estimated to be around 5 cm per year (Blanc 2002). As such, the presence of a population of monocaulous *Campylospermum* trees might be a good indicator of the age of the forest (Blanc 2002). The same author suggests monocaulous trees have a smaller chance of being damaged by falling branches or trees and thus form a good adaptation to life in the understorey.

A liana-like habit is reported on the labels of some herbarium sheets while few specimens are labelled as being scandent. However, it is difficult to judge the value of these statements, since such a habit could not be confirmed during one of our field trips.

- Ecology and phenology

In continental Africa, species of *Campylospermum* occupy a wide variety of habitats, but most species are found in the understorey of lowland evergreen or sometimes semi-deciduous forest or in forest edges and mixed savannah / forest vegetation. They are often found along rivers and streams, sometimes in swampy or flooded areas, but are absent from open savannah. Their occurrence thus seems to be related to two factors: light and humidity.

The vast majority of the continental African species is found in the lowlands, with only 10 out of the 48 species (21%) occurring at altitudes above 1500 m. The only truly montane species is *C. scheffleri* with an altitudinal distribution of 1400–2150 m. The close association of *Campylospermum* with lowland rain forest may be interpreted as an indication of niche conservatism (NC). This concept is applied when closely related

species share ecological similarities (Ricklefs 2010) and is defined as the retention of niche-related ecological traits over time (Wiens et al. 2010). Moreover, Ochnaceae species with winged seeds occur in open vegetation whereas, species with drupelets are generally found in closed-canopy forest, except for some *Ouratea* spp. and most *Ochna* spp. which occur in savannah-like vegetation (Amaral and Bittrich 2014). Ochnaceae species possibly retained their habitats from those of the ancestral tropical forest species that most likely occurred in warm, wet, closed or open canopy forest in the Mid-Cretaceous (Davis et al. 2005). In Africa, the tropical rainforest was fragmented several times during the Pleistocene glaciations (Sosef 1994; Couvreur et al. 2008). The exclusively occurrence of *Campylospermum* in these forests may be regarded as further evidence of NC. In order to test this hypothesis, environmental niche models that are able to statistically quantify niche (Warren et al. 2008) are required. NC may be an important concept to study speciation, historical biogeography and patterns of species richness (Wiens and Graham 2005). Moreover, understanding which factors control the distribution limits of *Campylospermum* species is crucial to be able to predict their responses to future global climate change.

In terms of phenology, flowering and fruiting of *Campylospermum* seems to take place all year round, but the peak flowering period is generally at the start of the rainy season, for instance September to October in Gabon or April to May in Cameroon. Individual flowers are open only during a short period of time, because the petals fall off quickly. Consequently, flowers and fruits from the same individual are rarely collected at the same time.

- IUCN conservation status

In *Campylospermum*, the number of known herbarium specimens per species ranges from only 4 (*C. lutambensis*) to 501 (*C. reticulatum*; Fig. 3). Some 17% of the continental African species of *Campylospermum* are only known from up to twenty specimens (*C. auriculatum*, *C. cabrae*, *C. descoingsii*, *C. klainei*, *C. louisii*, *C. lutambensis*, *C. nutans*, *C. paucinervatum*, *C. occidentalis*, *C. gabonensis*, *C. mannii* and *C. claessensii*). The average number of collections per species is 95. These figures show that the genus is well collected, but discoveries of new populations and even new species are to be expected on a regular basis.

In Chapter 3, a preliminary IUCN conservation status was assigned to all continental African *Campylospermum* species. The assessments were performed based on herbarium specimen data, supplemented with data on protected areas and a limited number of field observations. Most of the conservation assessments fall in the category of Least Concern except for fifteen species that have been assigned to the categories Vulnerable (*C. auriculatum*, *C. gabonense* (subsp. *gabonense* and subsp. *austral*), *C. louisii*, *C. occidentale* and *C. paucinervatum*), Endangered (*C. cabrae*, *C. descoingsii*, *C.*

klainei, *C. lutambense* and *C. nutans*) and Near Threat (*C. lecomtei*, *C. longestipulatum*, *C. manni*, *C. oliveri* and *C. umbricola*). The species from the Vulnerable category are exclusively or partly known from areas exposed to mining and/or logging activities rendering a decline in their AOO and most likely the quality of their habitats plausible. The species categorized as Endangered are known from less than twelve collections and mostly found in unprotected areas. The Near Threat species have been assigned to this category because they are only known from old collections, and so their occurrence needs confirmation. In addition, they have a fairly small distribution area where some of the populations occur outside protected areas.

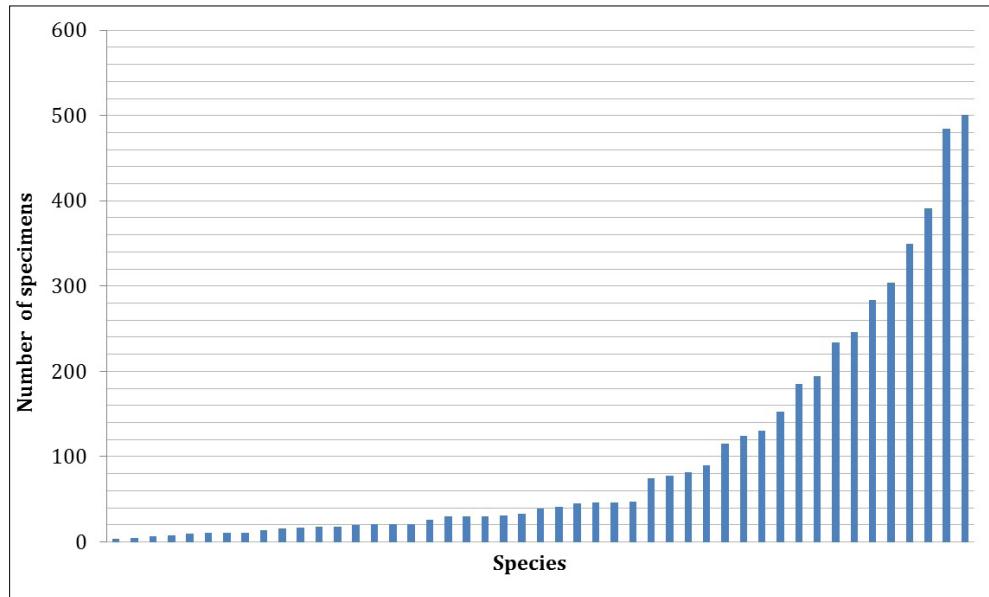

Figure 3. Number of herbarium specimens available per species. Each bar represents a single species of *Campylospermum*.

These assessments provided here can only serve as guidelines indicating areas where specific conservation efforts could be affected. For instance, *Campylospermum* species are relatively well distributed in areas with closed forest (Fig. 1). Species that occur in degraded forest of the Guinean face the largest threats of extinction. Those forests are most severely subjected to anthropogenic actions. Moreover, they are located near the Atlantic coast and outside mountain range, thus they are exposed to easy access by man, suggesting that conservation efforts should be prioritised in that region.

Furthermore, the assessments of the IUCN Red List categories of threat followed the IUCN guidelines (IUCN Standards and Petitions Subcommittee 2013). These guidelines advise to have a cell width of 2 km, but this turns out to be useless when working with herbarium records (Moat 2007) and a grid size of 2 km is often considered as being

too small. However, by using larger grid cells, the AOO of a species known from a single population could easily exceed 10 km². This will then never allow such a species to be assessed as Critically Endangered under criterion B2. Still, we agree with Moat (2007) and others (for example Sosef 2014) and deem the selection of an appropriate cell size for each individual species to estimate their AOO and EOO as the preferred method when using herbarium specimen data.

Summary

Chapter 1 provides an introduction to the organisms studied and the general aims of the project. The family Ochnaceae (Malpighiales) is divided into the three subfamilies Medusagynoideae, Quiinoideae and Ochnoideae, together comprising 32 genera and about 500 species. Ochnaceae are widely distributed in tropical and subtropical forests and savannas of the Old and New World. Medusagynoideae is a monotypic subfamily from the Seychelles Island, Quiinoideae occur in tropical America and Ochnoideae is a pantropical subfamily and includes one of the most species-rich genera: *Campylospermum* with about 55 species.

The goal of this PhD project was to unravel the evolutionary history and the historical biogeography of the family Ochnaceae, with special emphasis on the genus *Campylospermum* and its relationship with sister genera. Because the taxonomy of the species within this genus is unclear, a taxonomic revision was foreseen.

Chapter 2 presents the taxonomic novelties encountered within the genus *Campylospermum*. These comprise the description of five new taxa: *C. auriculatum*, *C. gabonense*, *C. gabonense* subsp. *australe*, *C. glaucifolium* and *C. occidentale*. Distribution maps of these taxa as well as preliminary assessments of their threat status following the IUCN criteria and guidelines are provided. In addition, new combinations were necessary for nine species: *C. andongense*, *C. costatum*, *C. glomeratum*, *C. longestipulatum*, *C. lunzuense*, *C. lutambense*, *C. nutans*, *C. plicatum*, and *C. warneckeii*, which were formerly assigned to the genera *Ouratea* and *Gomphia*.

Chapter 3 presents the taxonomic revision of the continental African species of the genus *Campylospermum*. It comprises 48 species, with *C. auriculatum*, *C. gabonense*, *C. louisii* and *C. occidentale* being strictly endemic to Gabon. A key to all taxa was constructed. Vegetative characters such as the leaf shape and venation, as well as inflorescence structure proved most useful to distinguish between species. Each taxon treatment comes with a detailed description, synonyms, typification (occasionally a lecto- or neotype had to be designated), distribution (including a map), habitat, uses, vernacular names, the citation of all specimens studied, and key literature. Additionally, the preliminary assessment of the IUCN conservation status of all species led to the assignment of a level of threat to 14 species. The remainder was categorized as Least Concern.

Chapter 4 presents a molecular phylogenetic analysis of Ochnaceae s.l. (with 94% of the generic diversity sampled), using four plastid markers (*matK*, *ndhF*, *rbcL*, *trnL-F*) and three parts of nuclear ribosomal DNA (ITS-1, 5.8S, ITS-2). The result of the Maximum Likelihood and Bayesian analyses generally showed strong support for the phylogenetic backbone of the family. A new classification of Ochnaceae, comprising the

subfamilies Medusagynoideae Reveal, Quiinoideae Luerss. and Ochnoideae Burnett is presented. The relationships between the monotypic Medusagynoideae and the other two subfamilies are poorly supported, but Ochnoideae and Quiinoideae form strongly supported clades. The analyses show support for a subdivision of the Ochnoideae into four tribes (Luxemburgieae, Ochneae, Sauvagesieae and Testuleeae), while within the tribe Ochneae three monophyletic subtribes (Elvasiinae, Lophirinae and Ochninae) can be recognized. The relationships between the genera of the Ochninae are poorly supported. Within Quiinoideae, the genera *Lacunaria* and *Touroulia* formed a clade sister to *Quiina*. A reconstruction of the ancestral character states using Bayesian approaches shows that zygomorphic flowers with adaptations to buzz-pollination, a syncarpous gynoecium, numerous ovules, septicidal capsules, and winged seeds with endosperm are the ancestral condition in Ochnoideae.

Chapter 5 provides a reconstruction of the phylogeny of Ochnaceae s.l., with emphasis on the subtribe Ochninae which contains the genus *Campylospermum*. We used three plastid DNA regions (*matK*, *rbcL*, *trnL-F*) and an intensified taxon sampling for the Ochninae. Our Maximum Likelihood and Bayesian analyses corroborate the phylogenetic backbone previously recognized in Ochnaceae. Within the genus *Campylospermum* two clades can be distinguished. The first comprises the West/Central African *Campylospermum* species while a second includes all East African and Malagasy species along with the West/Central African *C. elongatum*. Thus, there seems to be support for the recognition of subgenera, but we refrained from formalizing this because no Asian and only few of the Malagasy taxa were included in our sampling.

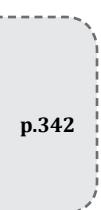

Chapter 6 aims to explore the possible historical biogeographic events that are responsible for the disjunct distribution of extant Ochnaceae species. To achieve this objective, divergence times within Ochnaceae are estimated and its biogeographic history reconstructed. Using five DNA sequence regions (ITS, *matK*, *ndhF*, *rbcL*, *trnL-F*), a secondary calibration, and relaxed molecular clock models provided by the software BEAST, divergence time estimations are obtained. Subsequently, Dispersal-Vicariance Analysis and Bayesian Binary MCMC implemented in RASP are used to reconstruct the biogeographic history of Ochnaceae. Divergence time estimates indicate that the Ochnaceae originated in the New World while the Old World was most likely colonized via the North Atlantic Land Bridge during periods when climatic conditions allowed the establishment of a boreotropical flora.

Chapter 7 highlights the main outcomes of all chapters of this thesis and puts them in the perspective of their contribution to society and to the science of systematics in particular. Various suggestions to explore different angles in future investigation are provided. The phylogenetic results presented in this thesis were based on concatenation methods and show that parts of the phylogenetic trees remain poorly supported.

Furthermore, the short internal branches observed may be interpreted as evidence of deep coalescence which can yield misleading results. This implies that further molecular phylogenetic studies are needed. It is also proposed to incorporate phylogenomics (using next generation sequencing data) and coalescent analyses to resolve these weakly supported parts and to reach a reliable estimate of Ochnaceae phylogeny. Species richness is unevenly distributed among the Ochnaceae subfamilies. Ochnoideae have by far the highest species richness, whereas Quinoideae have relatively few species and Medusagynoideae only one. It is suggested to investigate whether the diversity patterns could be the result of a difference in underlying evolutionary processes influencing diversification rates.

The taxonomic revision provides insight into the biogeographic patterns of the genus *Campylospermum*. The highest level of diversity and endemic species is found in the Congolian biogeographic region, especially in Gabon, where they are located in upland area identified as potential rain forest refugia. The Zambezian biogeographic region is less diverse and has few endemic species that are mainly found in the Eastern Arc mountain range in Kenya and Tanzania. Most of the *Campylospermum* species occur in lowland, only few are found at altitudes above 1500m.

The distribution of more fine-scale centers of diversity and endemism for the genus *Campylospermum* concur nicely with those postulated for other groups and might be related to Pleistocene climatic fluctuations and their major impact on the extent of lowland rain forest. It could be, however, that these patterns are affected by a collecting bias and further analyses should be performed taking these into account.

p.342

Samenvatting

Hoofdstuk 1 geeft een inleiding op de bestudeerde organismen en de algemene doelstellingen van het project. De familie Ochnaceae (Malpighiales) is opgedeeld in de drie onderfamilies Medusagynoideae, Quiinoideae en Ochnoideae, die tezamen 32 geslachten en ongeveer 500 soorten omvatten. Ochnaceae zijn wijd verbreid in tropische en subtropische bossen en savannes van de Oude en Nieuwe wereld. Medusagynoideae is een monotypische onderfamilie van de Seychellen, Quiinoideae komen voor in tropisch Amerika en Ochnoideae is een pantropische onderfamilie met daarin één van de meest soortenrijke geslachten: *Campylospermum* met ongeveer 55 soorten.

Het doel van dit PhD project was om de evolutionaire geschiedenis en de historische biogeografie van de familie Ochnaceae te ontwarren, met speciale aandacht voor het geslacht *Campylospermum* en haar relatie met andere zuster-geslachten. Omdat de taxonomie van de soorten binnen dit geslacht onduidelijk is, was een taxonomische revisie voorzien.

Hoofdstuk 2 presenteert de taxonomische nieuwigheden die we binnen dit genus aantroffen. Deze omvatten de beschrijving van vijf nieuwe taxa: *C. auriculatum*, *C. gabonense*, *C. gabonense* subsp. *australe*, *C. glaucifolium* en *C. occidentale*. Verspreidingskaarten van deze taxa als ook voorlopige beoordelingen van hun bedreigings-status volgens de IUCN criteria en richtlijnen worden gegeven. Daarboven waren nieuwe combinaties noodzakelijk voor negen soorten: *C. andongense*, *C. costatum*, *C. glomeratum*, *C. longestipulatum*, *C. lunzuense*, *C. lutambense*, *C. nutans*, *C. plicatum*, en *C. warneckeii*, welke voorheen waren toegewezen aan de geslachten *Ouratea* en *Gomphia*.

Hoofdstuk 3 presenteert de taxonomische revisie van de continentaal Afrikaanse soorten van het geslacht *Campylospermum*. Dit omvat 48 soorten, met *C. auriculatum*, *C. gabonense*, *C. louisii* en *C. occidentale* strikt endemisch voor Gabon. Een sleutel tot alle taxa werd vervaardigd. Vegetatieve kenmerken zoals bladvorm en nervatuur, alsook de structuur van de bloeiwijze bleken het meest nuttig bij het onderscheid tussen de soorten. Elke taxon behandeling gaat vergezeld van een gedetailleerde beschrijving, synoniemen, typificatie (soms moest een lecto- of neo-type worden aangewezen), verspreiding (inclusief een kaart), habitat, gebruik, inlandse namen, de citatie van alle bestudeerde exemplaren, en belangrijkste literatuur. Bovendien leidde de voorlopige beoordelingen van de IUCN beschermingsstatus van alle soorten tot de toekenning van een bedreigingsstatus aan 14 soorten. The rest werd ingedeeld in de categorie Least Concern.

Hoofdstuk 4 geeft een moleculair fylogenetische analyse van de Ochnaceae s.l. (met 94% van de generische diversiteit bemonsterd), gebruik makend van vier plastide markers (*matK*, *ndhF*, *rbcL*, *trnL-F*) en drie delen van kern ribosomaal DNA (ITS-1, 5.8S, ITS-2).

De resultaten van de Maximum Likelihood en Bayesiaanse analyses tonen doorgaans sterke ondersteuning voor de fylogenetische ruggegraad van de familie. Een nieuwe classificatie van Ochnaceae, met daarin de onderfamilies Medusagynoideae Reveal, Quiinoideae Luerss. en Ochnoideae Burnett wordt gepresenteerd. De relaties tussen de monotypische Medusagynoideae en de andere twee subfamilies zijn zwak ondersteund, maar Ochnoideae en Quiinoideae vormen sterk ondersteunde claden. De analyses tonen steun voor een onderverdeling van de Ochnoideae in vier triben (Luxemburgieae, Ochneae, Sauvagesieae en Testuleeae), terwijl binnen het tribus Ochneae drie monofyletische ondertriben (Elvasiinae, Lophirinae and Ochninae) kunnen worden herkend. De relaties tussen de geslachten van de Ochninae worden zwak ondersteund. Binnen de Quiinoideae vormen de geslachten *Lacunaria* en *Touroulia* een zusterclade van *Quiina*. Een reconstructie van de voorouderlijke kenmerktoestanden middels een Bayesiaanse benadering toont aan dat zygomorfe bloemen met aanpassingen voor “buzz” bestuiving, een syncarpe stamper, veel zaadknoppen, met kleppen openspringende doosvruchten, en gevleugelde zaden met endosperm de voorouderlijke toestand zijn binnen Ochnoideae.

Hoofdstuk 5 geeft een reconstructie van de fylogenie van Ochnaceae s.l., met nadruk op het ondertribus Ochninae welke het geslacht *Campylospermum* bevat. We gebruiken drie plastide DNA regio's (*matK*, *rbcL*, *trnL-F*) en een geïntensieveerde taxon bemonstering voor de Ochninae. Onze Maximum Likelihood en Bayesiaanse analyses ondersteunen de fylogenetische ruggengraat eerder herkend binnen Ochnaceae. Binnen het geslacht *Campylospermum* kunnen twee clades worden onderscheiden. De eerste omvat de West/Centraal Afrikaanse soorten van *Campylospermum* terwijl de tweede alle Oost Afrikaanse en Madagassische soorten bevat samen met de west/Centraal Afrikaanse *C. elongatum*. Dus, er lijkt ondersteuning te zijn voor het herkennen van ondergeslachten, maar we onthouden ons van een formalisatie hiervan, omdat er geen Aziatische en slechts enkele Madagassische soorten in onze bemonstering waren opgenomen.

Hoofdstuk 6 heeft als doel het ontdekken van mogelijke historisch biogeografische gebeurtenissen die verantwoordelijk zijn voor de disjuncte verspreiding van nulevende Ochnaceae soorten. Om deze doelstelling te bereiken worden divergentietijden binnen Ochnaceae geschat en haar biogeografische geschiedenis gereconstrueerd. Met behulp van vijf DNA sequentie regio's (ITS, *matK*, *ndhF*, *rbcL*, *trnL-F*), een secundaire calibratie, en “relaxed molecular clock” modellen voorzien binnen het programma BEAST, werden schattingen van divergentietijden verkregen. Vervolgens zijn Dispersal-Vicariance Analysis en Bayesian Binary MCMC geïmplementeerd in RASP gebruikt om de biogeografische geschiedenis van de Ochnaceae te reconstrueren. Schattingen van divergentietijden geven aan dat de Ochnaceae in de Nieuwe Wereld zijn ontstaan, terwijl de Oude Wereld hoogst waarschijnlijk werd gekoloniseerd via de North Atlantic Land

Bridge in tijden dat klimatologische condities de ontwikkeling van een boreotropische flora toelieten.

Hoofdstuk 7 belicht de belangrijkste resultaten van alle hoofdstukken van dit proefschrift en zet die in een perspectief van hun bijdrage aan de gemeenschap en aan systematische wetenschap in het bijzonder. Diverse suggesties om verschillende invalshoeken te exploreren tijdens toekomstige onderzoeken worden gegeven. De in dit proefschrift gepresenteerde fylogenetische resultaten waren gebaseerd op samenvoegende methodes en laten zien dat delen van de fylogenetische boom slecht ondersteund blijven. Bovendien, de waargenomen korte interne takken kunnen geïnterpreteerd worden als bewijs voor diepe coalescentie die misleidende resultaten kan opleveren. Dit impliceert dat verdere moleculair fylogenetische studies nodig zijn. Het wordt ook voorgesteld om fylogenomica (gebruik makend van next generation sequentie data) te incorporeren en coalescentie analyses om deze zwak ondersteunde delen op te lossen en een betrouwbare schatting van de Ochnaceae fylogenie te verkrijgen. Binnen de Ochnaceae onderfamilies is er een ongelijke verdeling van de soortenrijkdom. Ochnoideae hebben veruit de hoogste soortenrijkdom, terwijl Quiinoideae relatief weinig soorten hebben en Medusagynoideae slechts één. Het wordt gesuggereerd om te onderzoeken of deze diversiteitspatronen het resultaat kunnen zijn van een verschil in onderliggende evolutionaire processen die de snelheid van diversificatie beïnvloeden.

De taxonomische revisie geeft inzicht in de biogeografische patronen van het geslacht *Campylospermum*. Het hoogste niveau van diversiteit en aantal endemische soorten wordt gevonden in de Congolian biogeografische regio, vooral in Gabon, waar deze voorkomen in heuvelland dat geïdentificeerd is als potentieel regenbos refugium. De Zambesische biogeografische regio is minder divers en heeft minder endemische soorten, die vooral in de Eastern Arc bergen van Kenia en Tanzania worden gevonden. De meeste *Campylospermum* soorten komen voor in het laagland, slechts enkele worden gevonden op hoogtes boven de 1500 m.

De verspreiding van meer fijnschalige centra van diversiteit en endemisme van het geslacht *Campylospermum* komen fraai overeen met die gepostuleerd voor andere groepen en zouden gerelateerd kunnen zijn aan Pleistocene klimaatfluctuaties en hun grote impact op de verbreiding van laagland regenbos. Het zou echter kunnen zijn dat deze patronen beïnvloed zijn door een ongelijke verzamelintensiteit en verdere analyse dient uitgevoerd te worden die daar rekening mee houdt.

Résumé

Le Chapitre 1 présente d'une part, le groupe taxonomique étudié et ses sous-groupes, et d'autre part, les objectifs généraux de la thèse. La famille des Ochnaceae (Malpighiales) se subdivise en trois sous-familles, Medusagynoideae, Quiinoideae, Ochnoideae, réparties en 32 genres et 500 espèces. Les Ochnaceae sont répandues dans les forêts et savanes des zones tropicales de l'Ancien et du Nouveau Monde. La sous-famille des Medusagynoideae est monotypique et endémique des Seychelles alors que celle des Quiinoideae est uniquement trouvée en Amérique tropicale. Les Ochnoideae, par contre, sont pantropicales, incluant l'un des genres les plus riches en espèce, le genre *Campylospermum*.

Cette étude a pour objectif de reconstituer l'histoire évolutive et la biogéographie de la famille des Ochnaceae en mettant un accent particulier sur le genre *Campylospermum*, à travers notamment sa relation avec les genres voisins et une révision taxonomique permettant d'améliorer la délimitation de ses espèces.

Le Chapitre 2 décrit cinq nouveautés taxonomiques rencontrées dans le genre *Campylospermum*: *C. auriculatum*, *C. gabonense*, *C. gabonense* subsp. *australe*, *C. glaucifolium* et *C. occidentale*. Pour chaque taxon, des cartes de distribution ont été réalisées. Le statut de conservation de chaque espèce a fait l'objet d'une évaluation préliminaire selon les critères de l'IUCN. De nouvelles combinaisons sont proposées pour neuf espèces: *C. andongense*, *C. costatum*, *C. glomeratum*, *C. longestipulatum*, *C. lunzuense*, *C. lutambense*, *C. nutans*, *C. plicatum* et *C. warneckei*, qui étaient autrefois classées dans les genres *Gomphia* et *Ouratea*.

Le Chapitre 3 présente la révision taxonomique du genre *Campylospermum* pour l'Afrique continentale. Le genre comprend 48 espèces africaines, avec *C. auriculatum*, *C. gabonense*, *C. louisii* et *C. occidentale* strictement endémiques du Gabon. Pour chaque taxon sont présentés une description détaillée, une liste des synonymes avec citation des types, la répartition, l'*écologie*, les usages, les noms vernaculaires, et une liste des spécimens étudiés, et références bibliographiques. Les caractères végétatifs tels que la forme des feuilles et la nervation, ainsi que la structure des inflorescences, sont prépondérants dans la délimitation des espèces. Une clé d'identification des espèces est également proposée. L'analyse du statut de conservation de toutes les espèces a permis d'identifier 14 espèces menacées suivant les critères de l'IUCN.

Le Chapitre 4 présente l'analyse phylogénétique de la famille des Ochnaceae s.l. (94% des genres ont été séquencés), basée sur quatre marqueurs chloroplastiques (*matK*, *ndhF*, *rbcL*, *trnL-F*) et trois nucléaires (ITS-1, 5.8S, ITS-2). Il en ressort que, les résultats du Maximum de Vraisemblance et Bayesiennes montrent un support solide de l'arbre phylogénétique. Une nouvelle classification des Ochnaceae, comprenant les

sous-familles Medusagynoideae Reveal, Quiinoideae Luerss. et Ochnoideae Burnett, est présentée. La sous-famille Medusagynoideae est monotypique et occupe une position basale. Les Ochnoideae et Quiinoideae forment un clade robuste. Les analyses montrent également une subdivision des Ochnoideae en quatre tribus que sont: Luxemburgieae, Ochnaeae, Sauvagesiae et Testuleeae. La tribu des Ochnaeae se subdivise en trois sous-tribus monophylétiques, Elvasiinae, Lophirinae et Ochninae. Les relations de parenté entre les genres de la sous-tribu des Ochninae sont faiblement supportées. Dans la sous-famille des Quiinoideae, les genres *Lacunaria* et *Touroulia* forment un clade qui s'apparente aux *Quiina*. L'inférence des états de caractères ancestraux, en utilisant des méthodes Bayésiennes, suggère que les fleurs zygomorphes, adaptées à la pollinisation par vibration, ayant un gynécée syncarpe, plusieurs ovules, des capsules septicides, et des graines albuminées ailées, sont des caractères ancestraux chez les Ochnoideae.

Le Chapitre 5 traite de la phylogénie des Ochninae, comportant le genre *Campylospermum*. Trois marqueurs chloroplastiques, *matK*, *rbCL*, *trnL-F* et un fort échantillonnage des Ochninae ont été utilisés. Les analyses de Maximum de Vraisemblance et Bayésienne corroborent l'arbre phylogénétique précédemment reconnu. Deux clades se distinguent chez les *Campylospermum*: le premier comprend les *Campylospermum* de l'Afrique de l'ouest et centrale; le deuxième est constitué des espèces d'Afrique de l'est et de Madagascar ainsi que d'une espèce d'Afrique centrale, *C. elongatum*. Il semble ainsi avoir un support pour reconnaître des sous-genres au sein des *Campylospermum*. Nous n'avons toutefois pas étudié les espèces asiatiques, et seulement quelques-unes des espèces malgaches.

Le Chapitre 6 explore les possibles *événements historiques* ayant contribué à la distribution géographique actuelle des Ochnaceae. A cet effet, les âges de divergences chez les Ochnaceae ont été estimés et l'histoire biogéographique reconstruite. L'estimation des âges de divergence est réalisée en utilisant cinq régions de séquence d'ADN (ITS, *matK*, *ndhF*, *rbCL*, *trnL-F*), la calibration secondaire, et le modèle des horloges assouplies implémentées dans le logiciel BEAST. Les analyses de vicariance et Bayésiennes MCMC binaires implémentées dans le logiciel RASP ont été utilisées pour reconstruire l'histoire biogéographique des Ochnaceae. L'estimation des âges de divergence indique que les Ochnaceae sont originaires du Nouveau Monde et que l'Ancien Monde a été colonisé via le Pont terrestre nord Atlantique lorsque les conditions climatiques permettaient l'établissement d'une flore boréale tropicale.

Le Chapitre 7 présente les différents résultats de ce travail et met en perspective leurs contributions dans la société et la science, particulièrement en systématique. Différentes suggestions sont faites pour explorer d'autres champs de recherches. Les résultats phylogénétiques présentés sont basés sur la méthode de concaténation et montrent que certaines parties de l'arbre phylogénétique sont faiblement résolues.

De plus, les courtes branches observées dans l'arbre peuvent être interprétées comme résultant d'une «deep-coalescence» qui peut conduire à une mauvaise interprétation des résultats. Cela implique que d'autres études phylogénétiques doivent être faites, intégrant notamment des données génomiques (utilisant les données des séquences du **séquençage haut débit** et des analyses de coalescence). La prise en compte de ces données devrait permettre d'obtenir une phylogénie plus fiable et mieux résolue des Ochnaceae.

La richesse spécifique est très inégale entre les sous-familles des Ochnaceae. Les Ochnoideae ont le plus grand nombre d'espèces alors que les Quiinoideae en contiennent peu et les Medusagynoideae, une espèce uniquement. De nouvelles recherches sont proposées afin de voir si cette inégale répartition de diversité peut résulter d'un processus évolutif non connu, influençant le taux de diversifications.

La révision taxonomique a fourni des éléments sur la biogéographie du genre *Campylospermum*. La diversité et le taux d'endémisme sont élevés dans le domaine biogéographique Congolais, particulièrement au Gabon, où les espèces endémiques sont localisées dans les zones de montagnes identifiées comme potentiels refuges des forêts humides. En revanche, la région biogéographique Zambézienne ne compte que peu d'espèces endémiques, localisées principalement dans les montagnes de l'Arc oriental au Kenya et en Tanzanie. La plupart des *Campylospermum* se rencontrent à basse altitude, quelques-uns seulement dépassent 1500 m. La distribution des espèces de *Campylospermum* à une échelle plus fine correspond avec celle postulée dans d'autres groupes et peut être liée aux effets de fluctuations climatiques du Pléistocène et de leurs impacts sur l'extension de la forêt dense humide. Cependant, des sources de biais, telle que la densité des récoltes, peuvent affecter cette répartition et d'autres analyses doivent être faites pour prendre en compte ces biais.

Acknowledgements

I have gained ample experience as a scientist throughout this PhD period and I am thankful to everyone who contributed to accomplish this work.

My first thanks go to my promoter Marc Sosef for supporting this PhD project. I truly thank him for his guidance, background knowledge and time spent to improve the writing up of this thesis. PhD students are generally impatient for comments and suggestions from their supervisors to either conclude a work or carry on with another chapter. As such, he has always sent back his feedback on time and I really appreciated the regular flow of our emails. I also thank him for inviting me many times at his place or places such as the Delta Works, Kinderdijk, where I learned a little bit about the Dutch history, or culture. I really enjoyed those visits and his wife Susan is thanked for having made it possible.

I am grateful to my co-promoter Lars Chatrou who has accepted to shift from his group of interest Annonaceae to Ochnaceae during this PhD project. I thank him for his critical views and for proofreading my chapters. Knowing my educational background, he took his time to explain to me, sometimes from scratch, whenever it was needed. I thank him for that and also for his encouragements whenever I was worried about the load of my work.

I am grateful to Ludovic Ngok Banak for accepting to be my co-promoter from my home institute. My data collecting and part of my stay in the Netherlands was financially supported by one of the projects that he coordinated. I thank him to have facilitated, in many ways, this support.

I would like to extend my thanks to Henry Paul Bourobou Bourobou and Hilarion Mathouet, the Direction of my home institute IPHAMETRA (Gabon), as well as the former Directors Alain Souza and Marou Maroufath Lamidi, to facilitate all administration procedures during this PhD period.

I wish to thank Claude Farron who was very enthusiastic about the idea that we are following up on his Ochnaceae work. Many thanks for allowing the use of his Ochnaceae material.

My taxonomical revision was made possible by the use of herbarium specimens that were obtained on loan or studied in their respective institutes, and I am thankful to the curators from the following herbaria: A, B, BAS, BM, BR, BRLU, C, COI, E, EA, FHO, G, K, L, LBV, LISU, LY, MA, MO, NEU, P, PRE, S, SRGH, US, WAG, Z.

Special thanks go to Piet Stoffelen who made it possible to frequently visit the herbarium of Meise (BR).

Martin Cheek, from the herbarium of the Royal Botanic Gardens, Kew, is thanked to have facilitated my visit and organized my accommodation at Kew.

I owe a lot to Jason Randall Grant, the contact at the Neuchâtel herbarium, who handed over important Ochnaceae material to the Herbarium of the NHN Wageningen (now incorporated at Naturalis Biodiversity Center) as a gift. Among this material were the drawings by the late Sabine Bousani.

I thank Jan Wieringa from the NHN Wageningen who helped me databasing specimen information and geographic coordinates. Your wife Marjo is also thanked for inviting me many times at your place.

Folkert Aleva, Jan Janssen, René Siep, Koen van Setten, and all staff member of the NHN Wageningen are thanked for organizing the Ochnaceae loans.

I performed several field trips in Gabon, one with Dr. Frans J. Breteler from the NHN Wageningen whom I thank for his guidance. I also thank him for the many invitations for dinner at his place. I liked talking about our African experiences and play “Pétanque” with his wife Nardie to whom I also express my warm thanks. For their highly useful assistance during fieldwork, my thanks go to Valentin Boulanga, Jean Noel Boussiengui, Estelle Pauline Ngombou Mamadou, Raoul Nyangadouma, Christelle Roseline Nyangala and Thomas Nzabi all from the National Herbarium of Gabon.

For the field trip to Cameroun, I am thankful to Jean Michel Onana, the curator of Yaoundé Herbarium (YA), for organizing and coordinating my trip. Olivier Valerie Séne Belinga from YA is also thanked for assistance in the field.

I would like to thank Ria Vrielink for her training and assistance in the molecular laboratory and also Maria Samutina Kuzmina from the Biodiversity institute of Ontario (Guelp) for generating most of the sequence data for *Campylospermum*.

My gratitude goes to all the funding organizations that supported me during this PhD periods: Alberta Mennega Stichting, ACP-FORENET, Hugo de Vries Stichting and MOABI Foundation.

Wilma Twigt, I cannot thank you enough for your assistance in organizing everything concerning my stays in the Netherlands. Thank you for your help in translating from Dutch to English all documents related to my stay.

I have learned to have a time off for coffee or tea around 10 o'clock and I thank you all from the NHN Wageningen and Biosystematics group for sharing and creating a pleasant atmosphere.

I thank Jos van der Maesen from NHN Wageningen who invited me at his place as well as to choir concerts. I truly enjoyed those moments.

Paul Maas and his wife Hiltje from NHN Wageningen are also thanked to open their door to me.

I am thankful to my fellow colleagues for their valuable discussions and for sharing their views regarding this PhD project. My thanks go especially to Freek Bakker for his advices during my writing up period.

My sincerest thanks are addressed to Diana Quiroz and Setareh Mohammadin to have kindly accepted to be my paronymsphs. I wish you all well in finishing up your own PhD project.

As a foreigner, I cannot say that my stay in the Netherlands has always been splendid, but I felt less homesick and I am thankful to Anne, Annette, Cheron, Dolphin, Erica, Geanne, Geke, Gerard, Marieke, Martina, Mirjam, Muriel and Nadine for the quality time spent together. Thanks are also extended to the people from ICF, especially the WBS group.

Finally, my gratitude is extended to my family for their support and encouragement during this PhD period. To Ard and Marijke Louis who have been a source of knowledge to me. I am deeply touched by their involvement in my life.

My late father François d'Assises Bissiengou used to tell me when I was complaining about the load of my work that “ça va aller” meaning that everything is going to be all right. I guess he was right! I am so glad to have come to the end of this PhD road. My greatest thoughts go to him who provided constant encouragement and support during my entire educational process.

Curriculum vitae

Pulcherie Bissiengou was born on the 12th of November 1973 in Libreville, Gabon. She started her secondary education at “College Notre Dame de Quaben” and then, in 1997, went to complete her high school education in general science at the private school “Lycée Djoue Dabany” in Libreville, Gabon. In 1998, she moved to Franceville, Gabon, to start her university studies in General Science option Biology at the “Université des Sciences et Techniques de Masuku”, where she entered the three year Bsc program “Biology and Chemistry”. During the last year of the BSc programme, she undertook a practical course called “Bio-Traverse”, where she got the opportunity to learn about Gabon’s unique biodiversity by travelling from the South-East to the North of Gabon in order to study different types of ecosystems encountered in Gabon. Her passion to learn more about plants started at that period. In 2001, the Gabonese government granted her a scholarship to continue her studies in Stellenbosch, South Africa. After a year and half of learning English at Stellenbosch, she registered in the Department of Botany and entered a Master Degree course “Plant systematics and Biodiversity”. She first worked on a mini-thesis entitled “A morphological and anatomical comparison and profiling of selected *Agathosma betulina* and *A. crenulata* populations in the western Cape (South Africa)” then continued a major thesis on the “Taxonomic assessment of *Oxalis furcillata* (Oxalidaceae)”. She obtained her Master of Science degree in 2005. From 2006 up to now, she works at the National Herbarium of Gabon as a scientific staff member and has been involved in the production of the “Flore du Gabon” series. Her first work in that series is the treatment of the family Oxalidaceae, which was published in 2009. From 2009 to 2011, she coordinated the project Sud-Expert Plant 335: “Prospections botaniques et reliance du traitement des familles de la Flore du Gabon”. In August 2008, she obtained a sandwich grant from Wageningen University allowing her to start her PhD project at the Nationaal Herbarium Nederland – Wageningen branch on the systematics of Ochnaceae. In 2010, she undertook several field trips in Gabon and one in Cameroon for which she obtained an ACP-FORENET grant. Currently, she is aiming to publish, together with her promotor, the family treatment of the Ochnaceae in Flore du Gabon series, and also started to look at the Violaceae for the same purpose.

Phylogenetics, ancestral state reconstruction, and a new infrafamilial classification of the pantropical Ochnaceae (Medusagynaceae, Ochnaceae s.str., Quiinaceae) based on five DNA regions. *Molecular Phylogenetics and Evolution* 78:199-214.

PE&RC Training and Education Statement

With the training and education activities listed below the PhD candidate has complied with the requirements set by the C.T. de Wit Graduate School for Production Ecology and Resource Conservation (PE&RC) which comprises of a minimum total of 32 ECTS (= 22 weeks of activities)

Review of literature (5 ECTS)

- Systematics and evolutionary history of the African genus *Campylospermum* Tiegh. (Ochnaceae) (2008)

Writing of project proposal (4.5 ECTS)

- Systematics and evolutionary history of the African genus *Campylospermum* Tiegh. (Ochnaceae) (2008)

Post-graduate courses (3 ECTS)

- Advanced biosystematics course; Biosystematics group (2009)
- Seed morphology and anatomy; Leiden (2011)
- Introduction to R for statistical analysis; PE&RC (2013)

Laboratory training and working visits (4.5 ECTS)

- Herbarium visits; London (2009)
- Herbarium visits; Paris (2011)
- Herbarium visits; Meise (2012)

Invited review of (unpublished) journal manuscript (1 ECTS)

- Plant Ecology and Evolution: the genus *Idertia* (2013)

Deficiency, refresh, brush-up courses (3 ECTS)

- Phylogenetic reconstruction (2009)
- Taxonomic descriptions and nomenclature (2009)

Competence strengthening / skills courses (3.3 ECTS)

- Editorial skills for Flore du Gabon; Naturalis, Leiden (2009)
- Information literacy PhD including EndNote; WUR Library (2012)
- Scientific writing course; WUR language service (2013)

PE&RC Annual meetings, seminars and the PE&RC weekend (2.9 ECTS)

- PhD Day biodiversity (2009)
- PhD Day biodiversity (2011)
- PE&RC Last year PhD weekend (2013)

Discussion groups / local seminars / other scientific meetings (4.5 ECTS)

- Biosystematics group colloquia (2011)
- NHN-Leiden colloquia (2011)
- Biosystematics journal club (2012)

International symposia, workshops and conferences (8.1 ECTS)

- AETFAT; Madagascar (2010)
- Biodiversity and Conservation Genetics Research in Central Africa; Gabon (2011)
- Pro-iBiosphere workshop; Leiden (2013)
- AETFAT; South Africa (2014)

This PhD project was financed by a Sandwich PhD scholarship project funded by Wageningen University, IPHAMETRA (Gabon) and the National Herbarium of the Netherlands.

Visits to the herbaria K, P and BM were financially supported by the Alberta Mennega Stichting, the Hugo de Vries Stichting and MOABI Foundation. Additional funding was obtained from the Sud Expert Plantes (SEP) and African-Caribbean-Pacific Forest Research Network (ACP-FORENET) programmes, respectively to be able to work at the Wageningen herbarium and for fieldwork in Gabon and Cameroon.
