Abstract

A checklist of European Orthoptera is presented with indication of their sound production and the current availability of sound recordings on Xeno-canto. 926 out of 1232 Orthoptera species, or 75%, that have been reliably recorded in Europe produce sound. However, for just 802 (65%) of those species the sounds produced are meaningful for inventories and field identification. Sound recordings for 556 out of these 802 species (69%) are available now on Xeno-canto. The recordings are not spread evenly across Europe. Recordings are available for 190 of the 256 (74%) species occurring in the Iberian Peninsula; for 194 of the 230 species of Italy & Malta (84%); for 302 of the 374 of the species occurring in Balkan peninsula & Cyprus (81%); for 192 of the 218 of the species occurring in the North and Central Europe (88%) and for 168 of the 252 of the species occurring in the Eastern Europe (67%). The relatively high coverage of North and Central Europe is due to a combination of a relatively low number of species and a high density of sound recordists.

Keywords: bioacoustics, citizen science, open data, sound recordings

Zusammenfassung

Es wird eine Checkliste der europäischen Heuschrecken (Orthoptera) vorgestellt, mit Angaben zu deren Lauterzeugung und der aktuellen Verfügbarkeit von Tonaufnahmen ihrer Gesänge auf Xeno-canto. Von den 1232 zuverlässig in Europa nachgewiesenen Orthopterenarten erzeugen 926, also 75 %, Laute. Bei nur 802 dieser Arten (65 %) sind die Laute für Bestandsaufnahmen und die Bestimmung im Feld relevant. Für 556 dieser 802 Arten (69 %) sind derzeit Tonaufnahmen auf Xeno-canto verfügbar, doch sie sind nicht gleichmäßig über Europa verteilt. So sind Aufnahmen für 190 der 256 (74 %) Arten auf der Iberischen Halbinsel verfügbar, für 194 der 230 Arten in Italien und Malta (84 %), für 302 der 374 Arten auf der Balkanhalbinsel und Zypern (81 %), für 192 der 218 Arten in Nord- und Mitteleuropa (88 %) und für 168 der 252 Arten in Osteuropa (67 %). Die relativ hohe Abdeckung in Nord- und Mitteleuropa ist auf eine Kombination aus einer relativ geringen Artenzahl und einer hohen Dichte an Personen, die Tonaufnahmen erstellen, zurückzuführen.

Schlüsselwörter: Bioakustik, Bürgerwissenschaften, Gesangsaufnahmen, offene Daten

Introduction

There are few animal groups in which sound plays such an important role in their communication, ecology, identification and our general appreciation of them than Orthoptera. It is therefore no surprise that sound production by grasshoppers has received attention of researchers for a long time and morphological adaptations used for sound production or reception have always played an important part in the taxonomy of grasshoppers (Faber 1928, Faber 1953, Jacobs 1953, Willemse et al. 2009). In recent decades, publications on the identification of grasshoppers often contained verbal descriptions of vocalizations, sometimes accompanied by oscillograms (for instance Duijm & Kruseman 1983). However, for readers it is difficult to really understand what is meant when a sound is described in words. The first commercially available and larger collections of grasshopper sounds of European species were published by Grein (1984) and Bellmann (1985). The latter is the best known and consisted of a cassette with recordings of 56 species occurring in Germany. This was a valuable resource for people working on the Orthoptera fauna of Central Europe, even though the cassette contained some distorted sounds due to limitations of the recording techniques available at the time. An updated version with 59 species appeared in 1993 (Bellmann 1993) on Compact Disc (CD). The first extensive overview of sound recordings and sound descriptions of Orthoptera occurring in Western and Central Europe was published by David Ragge and Jim Reynolds (Ragge & Reynolds 1998a, 1998b). This publication was accompanied with compact discs with good sound recordings, allowing field workers to identify most of the northwestern European species by their sound. Several other publications of European grasshopper sound on CD or DVD followed in the following years including Bonnet (1995), Kleukers et al. (1997), Odé & Fontana (2002), Roesti & Keist (2009), Massa et al. (2012) and Sardet et al. (2015).

These publications, in combination with cheaper and better recording techniques becoming available, led to an increased use of sounds for species recognition. However, since the start of this century the number of commercially available publications of sound collections of European grasshoppers has declined, probably because of the CD and DVD losing popularity. This is why Willemse et al. (2018) published the sound recordings accompanying their field guide in an online repository. Alternative access to sound recordings is provided by the Orthoptera App (Rutschmann & Roesti (2024), also available through Orthoptera.ch) which contains recordings of all species occurring in Germany, Austria and Switzerland. Nowadays many recordings are available through online biodiversity portals, for instance through Observation.org or iNaturalist. Lower numbers of recordings but from a wide variety of species are available on the website Orthoptera Species File (OSF). Another source of sound recordings is bio.acousti.ca where about 600 recordings (50 hours) of about 140 species can be found. Recently two large datasets were published based on data from public sources with the main goal of facilitating the construction of sound recognition models of grasshoppers (Faiß et al. 2025, Funosas et al. 2025).

In September 2022, Xeno-canto (xeno-canto.org) opened up for the upload of sound recordings of grasshoppers. Xeno-canto is a web platform that since 2005 has offered (citizen) scientists and other enthusiasts the possibility to share wildlife recordings. It uses open-source code and Creative Commons licensing on recordings to facilitate sharing and reuse. Recordings and metadata are also shared through GBIF (Vellinga 2024). Until 2022, Xeno-canto focused on birds. It is currently the largest online open access repository for bird sounds containing over 900.000 recordings representing 96 percent of the species worldwide. To allow for the upload of grasshopper sounds the website was modified to also accommodate ultrasonic recordings. The taxonomic backbone was extended using the world checklist of Orthoptera Species File (OSF) (Cigliano et al. 2024). In order to speed up the upload of grasshopper recordings a series of bulk uploads were done in 2023 and 2024. Orthopterists with large sound collections were contacted and asked if they were willing to share their recordings with the wider orthopterist community. With a grant by NLBIF it was possible to assist them with the restructuring of metadata (information on locality and date) and help with bulk uploading of their recordings. As a result, over 32.000 recordings of nearly a thousand species became available online in a relatively short time. This includes valuable sound collections brought together during many years, or, in some cases, decades, of fieldwork by experts like Julien Barataud, Dragan Chobanov, Paolo Fontana, Klaus-Gerhard Heller, Sigfrid Ingrisich and Baudewijn Odé. The growth of the available recordings on Xeno-canto also stimulated others to start uploading their records and presently there is a steady flow of new recordings of grasshoppers being submitted.

At present over 32.000 recordings of grasshoppers are available on Xeno-canto, most of which are from Europe. For each recording an oscillogram, a spectrogram

and metadata including location and date is available (Fig. 1). In this paper we present an overview of the availability of sound recordings of European species on Xeno-canto. We hope that by providing this overview field workers will be stimulated to collect and share recordings, to document geographic variation and add species whose sounds are still not available or even completely unknown.

Fig. 1: Xeno-canto allows users to search sound recordings based on taxonomy or on location. For each recording an oscillogram, a spectrogram and metadata on the date and location are presented.

Material and Methods

The checklist included is based on Ivković et al. (2024) with some name changes and additions of newly described species to align with the taxonomy of the latest version of Orthoptera species file (Cigliano et al. 2024). The list includes all species found in Europe up to 2024. For the author and year of publication of the species we refer to Ivković et al. (2024).

Largely based on the expert knowledge of the first author, and with further input from AH, all species were divided in three groups: species with no known sound production, species which rarely make sound or in which the sounds are very weak (so not meaningful for field identification) and species producing sounds which can be used for species identification in the field. Furthermore, for all species the presence in five regions was indicated based on the regions used in Ivković et al. (2024): Iberia & Canaries (including Canary Islands, Madeira and the Azores); Italy & Malta; Balkan & Cyprus (with the northern parts of Serbia and Croatia included in N & C Europe); North and Central Europe; Eastern Europe (Belarus, Ukraine, Romania, Moldova, Russia and Georgia).

For each species and each country, the availability of recordings on Xeno-canto was summarized as the number of recordings available and the total duration of these recordings.

Results

Table 1 contains a checklist of the 1,232 European species indicating their distribution, their sound production and the availability of sound recordings on Xeno-canto. On 15th of March 2025 Xeno-canto contained 32,429 recordings of grasshoppers (over 860 hours) representing 981 species (3.3 % of the globally described species). Of these, 27,500 (84.9 %) belong to European species. Of the 1,232 species known to occur in Europe 262 (21.3 %) do not produce sound and 123 (10.0 %) only rarely make sound or only make very weak sounds. For 44 species it is unclear if they make sounds. The remainder (802 species, 65.2 %) produce sounds (sometimes ultrasonic) that are meaningful for species identification in the field. For 556 of these 802 species recordings are available on Xeno-canto. For 26 of the 246 European species for which no recordings are available on Xeno-canto one or more recordings can be found on orthoptera.speciesfile.org (OSF). For some widespread and common species such as *Tettigonia viridissima*, *Leptophyes punctatissima* and *Pholidoptera griseoptera* hundreds of recordings are available, but for most species only a handful or, in some cases, only a single recording is available.

Of the roughly 32,400 worldwide grasshopper recordings on Xeno-canto, about 22 % are constrained to audible frequencies (<20,000 Hz) due to lower sampling rates. The rest were recorded at higher sampling rates that make it possible to capture ultrasonic content.

The availability of recordings is not equally distributed across Europe (Fig. 2, Table 2). Recording activity is skewed towards Southern France (including Corsica), the Pyrenees, northern Italy and Greece, with smaller concentrations of records in the Netherlands and Montenegro. These are, except for the Netherlands, all species rich areas. Large parts of Spain, Portugal and Italy are species rich but clearly received less attention. Countries like Croatia, Bosnia Herzegovina, Serbia and Bulgaria are relatively species rich but are undersampled. This is especially true for Bosnia Herzegovina for which only one recording is available. Northwest and northern Europe is species poor and most species occurring there are well represented in the Xeno-canto database. Nonetheless it is a pity that for countries like the Czech Republic, Denmark, Estonia, Finland, Ireland, Sweden and Slovakia no or almost no records are currently available.

Table 3 gives the percentage of species for which sound recordings are available on Xeno-canto for each of the five main regions of Europe. For Central and Northern Europe close to 88 percent of the sound producing species recordings are available, with the species not included being either restricted in range or very rare. This high percentage is due to a combination of a relatively low number of species and a high density of sound recordists living in this region. The lowest coverage is found in eastern Europe (67 %), which is largely due to the scarcity of data from Russia. For the other areas, the coverage ranges from 74 to 84 %, with an average of 69 % for the whole of Europe. In absolute numbers the number of species lacking any recordings is highest in the Iberian Peninsula (66 species), the Balkan peninsula (73) and eastern Europe (84 species), with the latter mostly referring to species in the Ukraine or the southern parts of European Russia.

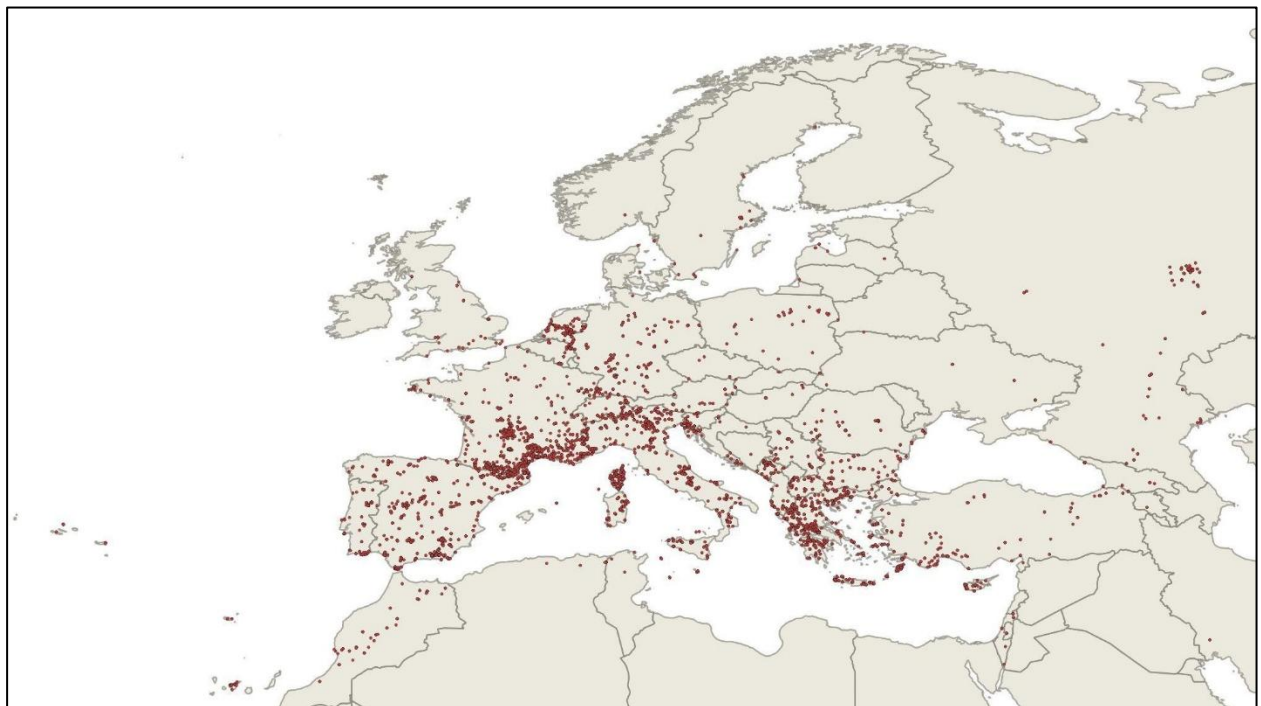

Fig. 2: Locations where sound recordings available on Xeno-canto were made.

Sound production is not distributed equally among the families and several, mostly small, families do not include any species producing sounds or sounds that facilitate identification: Dericorythidae, Myrmecophilidae, Pyrgomorphidae, Rhapsiphoridae, Tetrigidae and Tridactylidae. Together the large families of Acrididae and Tettigoniidae contain over 746 of the 803 (93 %) of the sounds producing European species. See Table 4.

For 23 European genera no recordings are available on Xeno-canto, many of which are represented in Europe only by one species. These include relatively many genera only found in eastern Europe (mostly Ukraine and Russia: *Aparapholidoptera* (1 species; recordings present on OSF), *Eremippus* (6), *Euconocercus* (2), *Gryllopsis* (1), *Isoimon* (1), *Lithodusa* (1), *Phonochorion* (1), *Phytodrymadusa* (1), *Schizonotinus* (3) and *Miramiola* (1). Genera with no recordings occurring in other parts of Europe are *Baratia* (1 species, Iberia), *Coracinotus* (3, Iberia; recordings of *Coracinotus notarior* available through OSF), *Cycloptiloides* (1, Canary Islands; recording available through OSF), *Evergoderes* (1, Iberia), *Exodrymadusa* (1, Balkan), *Eyprepocnemis* (1, Mediterranean), *Oedaleus* (2, Mediterranean), *Praephippiger* (1, Italy), *Rammehippus* (1, Balkan) and *Stenonemobius* (2, Mediterranean).

Table 1: Checklist of Orthoptera of Europe based on Ivković et al. (2024). For each species the general distribution, the sound production, the number of recordings on Xeno-canto and the total duration of these recordings is given. For those species for which no recordings are available on Xeno-canto the availability of recordings on orthoptera.speciesfile.org is indicated with ‘OSF’ in the last column. The species are divided into three groups based on the relevance of sound for identification and inventory: 0 – species not known to produce sound; 1 – species produce sound but sound is deemed of little relevance for identification as it is produced either very irregularly or it is generally not audible; 2 – species produce sound meaningful for identification and inventories.

Discussion

In a relatively short period of time, Xeno-canto has become a valuable source of information on the sounds of European grasshoppers. Recordings of 556 of the 802 (69%) European species producing sound meaningful for identification and inventory are already available on Xeno-canto with one or more recordings and in most areas of Europe the vast majority of the commonly encountered species is represented on Xeno-canto. This has only been made possible due to the willingness of people to share recordings.

In the bird community, AI-based sound recognition is already an established means of identification and many bird watchers throughout the world already use apps like BirdNET and Merlin for help with the identification of sounds. Naturalis Biodiversity Center (Leiden, Netherlands) is working on sound recognition models for European grasshoppers, and a first version will be available in 2025. The underlying algorithm will be published open access as part of the EU Horizon project TETTRIs. In order to include a species in these models at least five recordings of a species are needed. Because of this 87 species with recordings currently cannot yet be included in the models. As a result, with the current availability of recordings 468 of the 802 (58%) European species making sound meaningful for identification can be included. It is expected that in the next few years many new recordings will become available so that the percentage of species included in the models will increase with each published update. The influx of additional recordings will also improve the sound recognition quality of the model over time.

Table 2: Availability of sound recordings per country. * The data for Russia and Turkey also includes recordings from the Asian part of the countries.

Country	Number recordings	hours/minutes/seconds

In addition to serving as identification tools for specialists and citizen scientists the sound recognition model will also be used for monitoring. Xeno-canto also contains sound libraries for bats, amphibians and land mammals, and the long-term aim is to make sound recognition that can analyze soundscapes. When successful, this can be applied for transect monitoring in which repeated sound recordings across a transect are used to monitor changes in birds, mammals, amphibians and grasshoppers. A first demonstration of the possibilities for this for Orthoptera was published by Bennett et al (2025) who showed that 86.4 % of the sound recordings of a set of 20 species were identified correctly. Applying these methods is especially valuable in areas where citizen scientists are scarce or in areas that are less attractive to monitor such as large-scale agricultural areas. Sharing recordings on Xeno-canto thus makes it possible to allow others to enjoy the audio diversity of nature and to help develop new methods to monitor biodiversity.

Table 3: Taxonomic coverage of recordings on Xeno-canto in the main European regions.

	Europe	Iberia & Canaries	Italy & Malta	Balkan & Cyprus	C & N Europe	E Europe
Total number of species	1232	413	355	558	315	382
Number of species in category 2	802	256	230	374	218	252
Number of category 2 species for which recordings are available	556	190	194	302	192	168
% of category-2 species for which recordings are available	69.3%	74.2%	84.3%	80.7%	88.0%	66.7%

Table 4: Diversity of the 14 families of Orthoptera found in Europe with percentage of species producing sound meaningful for identification or inventory.

Family	Europe	Species in cat 2	% species in cat 2
Acrididae	368	176	47.8
Dericorythidae	5	0	0.0
Gryllidae	73	33	45.2
Gryllotalpidae	14	14	100.0
Mogoplistidae	11	1	9.1
Myrmecophilidae	11	0	0.0
Oecanthidae	3	3	100.0
Pamphagidae	71	0	0.0
Pyrgomorphidae	6	0	0.0
Rhaphidophoridae	70	0	0.0
Tetrigidae	14	0	0.0
Tettigonidae	572	569	99.5
Tridactylidae	6	0	0.0
Trigonodiidae	8	6	75.0

Acknowledgements

The work on the upload of grasshopper recordings was made possible by a grant of NLBIF. Work on sound recognition of grasshoppers is conducted as part of the EU Horizon projects TETTRIs and MAMBO. Views and opinions expressed are however those of the author(s) only and do not necessarily reflect those of the European Union or REA. Neither the European Union nor REA can be held responsible for them. We thank Milan van Hirtum for his work on helping with uploading some of the larger collections of sound recordings. We are grateful to the community of grasshopper enthusiasts for uploading large amounts of valuable recordings to Xeno-canto. Special thanks is due to Julien Barataud, Dragan Chobanov, Paolo Fontana, Klaus-Gerhard Heller and Sigfrid Ingrisich for making their very extensive collections of recordings available.
